Q.: So far as concerns the photographer's right and liability in regard to the sitter, I think we appear to have exhausted the subject for the present, but there are yet one or two points as regards ownership of copyright which I would like to explain. To give an example of what frequently occurs: I obtained permission some years ago to photograph the interior of a local church. On recently issuing a postcard of the subject the vicar now tells me I have no right to do so, and that I must withdraw it.

A.: You are entirely within your rights, and the same thing applies to photographs which, by hook or by crook, a photographer may make in places where photography is forbidden, or where the sole right to photograph is let out to a particular photographer for a sum of money. It may not be good to make use of what has been acquired by stealth, but that is nothing to damage your copyright in such views. The objections of the vicar, for example, are either made in ignorance or are only bluff.

Q.: A similar case is sometimes met when one is photographing a street scene and certain figures appear large enough in the photograph to be recognisable. I have had parties object to the issue of the photographs, but from what you say they are, so to speak, without a leg to stand on.

A.: The cases are not quite parallel, although in the matter of copyright they are. But it may happen that your photograph may—without any such intention on your part—represent persons in such a way that it may disparage, libel, or prejudicially affect them in a social or commercial way, if that is the case they may be able to make you withdraw the copies from circulation. For example, if a snapshot which you (as a seaside photographer) may have taken of a troupe of pierrots reflects unfavourably on their personal attractions there is good reason to suppose that its sale would harm attendances at their performances, and they would probably succeed in getting its sale stopped.

Q.: I must ask you now as to photographing paintings, engravings. I am occasionally asked to photograph paintings and copies of paintings, and there is always a doubt as to whether such work does not expose me to action for unlawful copying.

A.: In the case of original Old Masters there is, of course, no copyright, and they can be copied by anybody fortunate enough to get permission. It may be taken for granted, though, that all copies of them are copyright. The Act allows copyright to exist in any number of separate copies of a work of art, practically every copy is made solely with a view to charging fees for its reproduction. Hence caution should be exercised in making any further reproduction without permission.

Q.: Are engravings on all fours with paintings?

A.: No, the law is different. Whereas paintings and photographs

are placed on the same basis as regards the duration of it in them—that is to say, the copyright lasts for the the author and for seven years after his death—an ang enjoys protection for twenty-eight years from the date publication, which date should be stated on the print. erefore usually safe to copy an old engraving, since the ht in anything older than twenty-eight years will have

(To be continued.)

## THE ORIENT IN WELLINGTON STREET.

NTING's photographic studies of scenes and people in Japan er countries of the Far and Nearest East continue to attract ed visitors to the "little galleries" at the house of the where they are being shown until April 19. It will interest itors when we say that Mr. Ponting has in all a series of an half a hundred views of Mount Fuji. These are the of many weeks of work during his three pilgrimages to Japan, ow it at all seasons of the year. Mr. Ponting has tramped nes round the mountain—a circuit of over 100 miles—and has ascended it. The Kaia grass picture alone was only obtained rumping the twenty mile return journey from Shoji over a times. In a district so wind-swept as that is, only one who l the experience can appreciate the patience needed to get rone foregrounds, and a mountain twenty miles away, on one e same plate. All these results and more were also secured oscopic form for the H. C. White Co., 110, Strand, London, om Mr. Ponting made a set of stereoscopic plates. The Hundred Views of Fuji," by Hokusai, the great painter of e bourgeois life as well as scenery, were what gave our or the idea of making a series of photographic views of this s mountain, but the unfavourable weather so often ered impelled him to give the work up long before he had re near completed it. So far as he got with the work, how- can be said that when he published a simple half-tone album ty-five of the views it was received with immense enthusiasm, y by the entire foreign community in Japan, who, to a man, o the mountain's beauty almost as the Japanese themselves, the Japanese also, and the first edition of 2,000 copies sold most immediately.

reception of these studies of Fuji may be judged by an from the writings of a living authority on Japan. Professor Chamberlain, joint author of "Murray's Guide to Japan,"—"In fact, it would scarcely be an exaggeration to say r. Ponting has discovered a new mountain; for no one had en the great quiescent volcano depicted from so many spots except, indeed, from the pencil of Hokusai. But, then, thisainter gave representations which were half true, half fanciereas the album before us is pure and unadulterated truth." he present exhibition, the "Morning Post" says: "No doubt eaders will remember Mr. Ponting as one of the most success- those who obtained photographs illustrating the Russo- se War. The salient feature of the present exhibition is the ence given to 'Mount Fuji,' of which there are no less than ferent versions. Mr. Ponting was so fascinated by this est mountain in all the world" that he spent many weeks ng it from all sides."

"Photographic News" writes:—"Here we see at first hand vironment of the Japanese at home disclosed as possibly no camera has presented it; and as only photography in clever can present it. Mr. Ponting is to be congratulated on his llection, which owes in this case not a little to the splendid rk in the shape of enlarging, finishing, framing, and, in ases, colouring, the prints by Messrs. Raines, of Ealing. rints are masterpieces of fine work that speak volumes for the ities of this famous firm, and the splendid, but reticent ng in many cases would probably delight the heart of the se artists themselves."

"THAMES" SCREEN PLATE.—The first demonstration of the es" screen plate (Finlay's patent) will be given, by Mr. C. L. himself, at the London and Provincial Photographic Associa- ld Napier Tavern, 25, High Holborn, London, W.C.

## DEATH OF MR. A. S. SPRATT.

WE very much regret to announce the death of Mr. A. S. Spratt, which took place on March 25, at the end of a painful illness. Mr. Spratt has passed a long and honourable career in the photographic trade, and at the time of his death was a director of the firm of Houghtons Ltd. He had previously built up the business of Spratt

THE LATE A. S. SPRATT.

Bros. at Hackney, where for many years he, with his brothers, had directed the extensive manufacture of tripods, cameras, and other articles used by photographers. On the amalgamation of his firm with Messrs. Houghtons Ltd., Mr. Spratt transferred himself to the large works of the latter company at Walthamstow, and his colleagues, both there and at the High Holborn offices of the firm, will, with many others in the photographic world, regret his decease.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between March 16 and March 21:—

ARTIFICIAL LIGHT.—No. 5,960. Improvements in and relating to apparatus for printing photographs on postcards and the like by artificial light. Augustine Kerkham, 19, Holborn Viaduct, London.

FRAMES.—No. 6,372. Improvements in or relating to frames for pictures and the like. The Rotary Photographic Company, Ltd., 55, Chancery Lane, London:

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

CINEMATOGRAPHS.—No. 3,987. Plate for cinematographic projec-

tions, and process of, and apparatus for, the manufacture of the same. Muller and Rousset.

**FOLDING CAMERAS.**—No. 20,989. 1907. The invention consists of a folding camera, in which the lens-board is brought out of the camera into position for use by turning down the baseboard, and is returned to its original position upon releasing the latter. The essential feature of the invention is a pair of levers, jointed together and operated at one end of the camera struts. They are so arranged that the end not so attached describes a straight movement along the baseboard and moves the lens-board.

$n, q$  are the pair of levers jointed together, the lever  $n$  being hinged to the baseboard and gearing with the rack  $k$  by means of the toothed segment  $m$ . The lever  $n$  is made to rotate upon its hinge centre at the displacement of the slide  $e$ , and for this purpose a toothed wheel  $l$ , corresponding in its dimensions with the toothed section  $m$ , is rigidly mounted upon the axis of the lever  $n$ , but out of gear with the rack  $k$ . Two toothed wheels  $o$  and  $p$  half the size of the toothed wheel  $l$  are rotatably attached to the lever  $n$ , and geared together. The toothed wheel  $p$  is attached

to the lever  $q$ , which therefore passes through the same phases of movement as the toothed wheel. Both toothed wheels,  $o$  and  $p$ , are made to describe a rotary movement when the lever  $n$  is swung upon its axis, as the toothed wheel  $o$  gears with the stationary wheel  $l$  and the end  $r$  of the lever  $q$ , connected with the wheel  $p$ , is caused to pass along a straight line, describing a forward movement when opening, and a receding movement when closing up the camera. The free end  $r$  itself is held within the hook  $s$  by means of a projection. The hook  $s$  is pivoted at  $s^1$  to the slide  $t$  of the lens-board or panel  $u$ . The end  $r$  therefore forces the objective-slide along with it in its straight movement. The lens-panel  $u$  is hinged to the slide  $t$  by the hinge  $v$ , so that it is parallel to the baseboard  $b$  when the camera is closed up. Newnham Browne and Co., for the Emil Wünsche Aktiengesellschaft für Photographische Industrie, Reick, Dresden, Germany.

**TELEGRAPHIC TRANSMISSION OF PHOTOGRAPHS.**—No. 5,187. 1907.

The invention relates to a process of distance transmission of photographs, etc., in which the variations of conductivity of the original to be transmitted are utilised in a transmitter to act on a telegraphic circuit which includes at the receiving station, a telephone receiver or a polarised or non-polarised electro-magnet, the flexible diaphragm of which thus receives movements proportional to the variations and sufficiently great to engrave on a metal surface or reproduce the original in other ways. Every time that the pen or needle in question meets a point covered with material of different conductivity, the intensity of the current changes for a period of time in proportion to the length of the point, and the modification of current is transmitted by the line circuit to the receiver, which can be identical with the transmitter, except that the needle of the latter is replaced by a telephone receiver, of which the vibrating diaphragm is provided with a suitable engraver's point, which registers the different interruptions of current on a suitable surface, such as metal, gelatine, collodion, etc. The transmitter and the receiver must evidently be operated synchronously.

In this process the differences in the constitution of the layer of gelatine, collodion, etc., of the photographic plate (in the case of the transmission of a photograph) play the part of microphonic contacts which faithfully reproduce the half tones of the original. In fact, the pictures or photographs with salts of silver, platinum, etc., formed on or in the body of the layers or supports of gelatine, etc., are produced, as is well known, by a more or less uniform

distribution of the salts reduced to metallic state by the action of light. The layer retaining the metal forming the picture is, however, a practically uniform thickness, and consequently a practically constant electrical resistance at all the points in the direction perpendicular of its thickness. But the more or less proportion of metal retained by the layer of gelatine, etc., forming the picture modifies the resistance by reducing it more or less according to the proportions of metal which constitute different points of the picture. If, therefore, the latter is printed or transferred to a surface conducting electricity, each point of layer of gelatine, etc., in the direction of thickness, on passing under the point or the needle or stylo of the transmitter above mentioned, will vary the resistance of the circuit to a more or great extent. The effects produced on the armature of the receiver will, therefore, be similar to those produced by a microphone, the engraver's point of the receiver will penetrate to a greater or less depth into the layer to be engraved, according to resistance of the point which moves under the needle of the transmitter. In this way the receiver faithfully reproduces the original image with all its details.

When the negative or plate block in the transmitter is constituted by a so-called "carbon-photograph," the present process utilises the fact that the layer retaining the pigment, is more or less thick at the different points of its surface, practically in proportion to the shades and lights of the picture. It follows from that the resistances in the layer differ in accordance with the thickness of its different points. These resistances influence the current transmitted by the circuit to the point or stylo of the receiver, which will engrave in the receiver layer or surface point of depth corresponding to the reliefs and intaglios of the original of the transmitter.

When the original plate is constituted by a picture striped or grained in any way, the hollows between the different stripes, grains, etc., are all of the same depth, but the spaces between stripes, points, etc., are proportional to the lights of the picture. The currents acting on the receiver are in this case interrupted at the transmitter for a more or less long time, according to tones of the original picture. In this case the transmission may be effected with a plate photo-engraved on a suitable surface, with a copy printed from the plate. Nevertheless, in order to avoid the work of photo-engraving, it is more simple to use an image or copy grained or striped by photo-printing or other lithographic means or by other ordinary processes.

For the transmission of writing or drawings, the process may be carried out in several ways. It is possible to write or draw direct on a conducting surface metal sheet by means of a pen or drawing instrument, or it is possible to write or draw on lithographic transfer paper and to transfer on to a metal or conducting surface. The latter is then provided with the original reversed, and engraving received at the receiver can serve directly for printing numerous copies of the message received. If the original written, etc., be not reversed at sending off, it is sufficient to advance the receiver in the opposite direction to the transmitter in order to obtain in the former an engraving capable of being used direct for printing.

The half-tones of the picture can be reproduced at the receiver in several ways, either on a layer of any suitable material, hollows in proportion, or in inverse proportion, to the lights and the means already indicated; or on a layer of material by hollows of the same depth but of different surfaces; or on a layer of surface covered with a second layer of comparatively small thickness, of which the tonality is removed by the point or stylo of the receiver for forming the hollows or the contrasts. If the second layer be more or less transparent according to its thickness, it can also be more or less completely removed, in proportion to the shades of the original image.

As original may be used a tin foil on which the engraving photograph, etc., has been printed, written, drawn, etc., with printer's ink. The tin foil is then stuck on to a sheet of paper which renders it stronger. The tin foil is a conductor, whilst the image printed with printer's ink forms the non-conducting layer.

In order to make contact with the metal cylinder of the apparatus, the tin foil on which the original is printed or written is bent around the longitudinal edges of the paper backing

placed on the metal cylinder, so that the tin comes into direct contact with the latter when pressed in position.

For receiving an image direct, white paper covered with carbon paper may be placed on the receiver cylinder, the rounded off or blunted pin or stylo of the telephone vibrating against the carbon paper. This is important for receiving telegrams, engravings, and photographs, of which it is desired to obtain quickly only one copy.

For the printing on paper or on other material of the engraved plates received at the receiver, the said plates may retain the cylindrical shape to be employed direct on a circular press, or they may be straightened for printing on any press. Henri Carbonelle, 60, Chaussée de Ruysbroek, Uccle, Brussels, Belgium.

INEMATOGRAPH MECHANISM.—No. 10,078, 1907. The object of the invention is to prevent ignition of the films and to provide means in the case of fire or tearing of a film to turn on the lamps or other illuminating devices lighting the hall or other place where the apparatus is used.

The film is protected from the light as it passes through the machine, and is covered where the greatest amount of light is developed by a rotary shutter flap, which is raised, but only when the number of revolutions of the actuating device is normal, in such a manner that the light may enter in full strength. It is gradually closed when the number of revolutions is reduced, whilst should a tearing of the film occur a device is released which couples the actuating apparatus with the flap and returns the flap suddenly to the closed position. The device is also arranged so that when the film is torn the actuating apparatus is stopped and a device that effects the ignition of the lamps or other illuminating devices in the place occupied by the spectators is operated. Emil Gottlieb Homes and Julius Oszkar Gindert, 10, Kohlmarkt, Vienna.

### New Trade Names.

"STORRICO."—No. 297,850. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives, but not including caustic soda or chloride of lime, and not including goods of a like kind to any of these excluded goods. Storry, Withson, and Co., Limited, Bankside Works, Sculcoates, Hull, and colour manufacturers. November 9, 1907.

### Analecta.

*Extracts from our English weekly and monthly contemporaries.*

#### The New Lippmann Method of Stereoscopic Photography.

WRITER in the current issue of "The Amateur Photographer," in dealing with Professor Lippmann's new method, says: We can now give some details as to the actual means that may be adopted for producing a cellular film or texture which virtually consists of a number of minute tubes packed side by side and blackened inside, each tube containing a miniature Stanhope lens. Here is a possibility. A sheet of celluloid is moulded between two exactly registering and properly patterned hot plates, so as to produce a thin celluloid film, out of which rise pillars or cylinders of celluloid, the results being something like the cash mats used in shops, but much finer, and in transparent celluloid. The mould would naturally be figured as to give the top of each projecting cylinder the curved shape of the Stanhope lenses, the more curved end of each "lens" being at the top of the projecting cylinder, and the less curved end being on the remote surface of the connecting film. The interspaces between the cylinders being now filled in with black pigment, and the more even surface of the celluloid being coated with sensitive emulsion, all will be ready for exposure, and this exposure will be through the support, as in the Autochrome process, but no lens will be required, and the camera may be of the most rudimentary kind; indeed, nothing more than a dark slide and draw-shutter or other device for exposures. The first result will be a negative, but by taking advantage of a method of reversal similar or comparable to that of the Autochrome process, this can be converted into a positive.

The result will have within itself the elements of many stereoscopic aspects, as from any one standpoint an eye will only see one portion of each minute image, and the whole image formed by a combination of these points will change in orientation owing to different combination of these points, hence the ordinary view with two eyes should always be stereoscopic. How far this prospective wonder in photography will be actually realised can scarcely be guessed, but the main difficulty is one that is purely constructive, that of making the cellular and lenticular base, and this may only be a question of organisation and manufacture. Professor Lippmann has a few results which clearly show possibilities, but we may conjecture that when the cellular basis can be produced at a moderate price, and with the cylindrical cells about half a millimetre in length, and one-fourth of a millimetre in diameter, the method will have interest from what is commonly called the practical point of view, as this may give a sharpness approximating to the one-hundredth of an inch standard.

### New Apparatus, &c.

The "Merito" All-Ways Adjustable Vignetter. Made by W. L. Parkinson, Ltd., 5, Commutation Row, Liverpool.

A simple and very inexpensive form of vignetter is this new introduction of Messrs. Parkinson, which consists of a cardboard frame to fit over the printing frame. It is supplied with a double cover, between which discs pierced with openings of various sizes and

shapes can be instantly inserted and adjusted in position. The depth of the frame allows of the vignetter being packed up at various distances from the negative, and the construction of the vignetter secures the negative from all light other than that passing through the vignetting aperture. The price of each vignetter, complete with three shapes and one blank disc, is 6d. in quarter-plate size, 9d. in half-plate. Extra vignetting shapes are obtainable in boxes of six at 6d.

The No. 2A "Brownie." Made by Kodak, Ltd., 57 to 61, Clerkenwell Road, London, E.C.

A new size of the ever-popular "Brownie" camera reaches us from the Kodak Company. The picture taken measures 4½ in. by 2½ in.,

a shape very similar to that of the postcard, though of slightly smaller dimensions. Nevertheless, a No. 2A "Brownie" negative printed with a border permits of the ready production of photo-

graphic souvenirs in postcard form. The little camera, which measures externally 6in. by 3½in. by 5in., is fitted with horizontal and vertical finder, achromatic lens, e-r-set shutter, giving instantaneous and time exposures, and a set of three diaphragms. It is, of course, for roll film, and takes a twelve-exposure spool of the size made for the No. 1a folding pocket Kodak. The camera, which has all the advantages of the daylight loading system, is sold for 12s. 6d.

The No. 2 "Brownie" Enlarger. Made by Kodak, Ltd., 57 to 61, Clerkenwell Road, London, E.C.

The convenient form of this fixed-focus enlarger will recommend it to many boy and girl users of the popular "Brownie" cameras. The instrument takes the 3½in. by 2½in. negatives of the No. 2 "Brownie," and the 2½in. square negatives of the No. 1, the former giving a 7in. by 5in. enlargement and the latter one 5in. by 5in. The manipulations are obviously reduced to the simplest possible form, and the enlarger, which costs 10s., should be popular with every user of the series of small cameras introduced by Kodak, Ltd.

## New Materials, &c.

**POSTCARD TITLE BORDERS.**—A new device for the simultaneous printing of the negative and the title in black letters on a white margin is being put on the market by Mr. A. W. Bowen, of 193, High Street, Watford. It consists of an opaque, flexible mask, composed apparently of a gelatine film stripped from glass and rendered opaque with a special pigment. On one inside edge of this film the title of the subject appears in transparent letters, so that the only operation necessary when printing the postcard is to scrape away a little of the film from the negative so as to give a transparent space underneath the lettering. The printing of both landscape or portrait and the title can then be done by the single operation. The prices and styles of these new mounts can be obtained from Mr. Bowen.

**WRATTEN LIGHT-FILTERS.**—Messrs. Wratten and Wainwright have prepared a card of small samples of their K<sub>1</sub>, K<sub>2</sub>, and K<sub>3</sub> orthochromatic filters, and of their set of tri-colour filters. This card of specimens is sent free for one penny stamp.

**STAND DEVELOPMENT.**—In reference to our notice of his metallic supports for "stand" development of plates in ordinary dishes, Mr. F. C. Clarkson writes from Colchester: "I am afraid some may court disaster if experimenting with film up—there would almost certainly be reticular markings with some developers. To place four half-plates or eight quarter-plates in 10 by 8 dish they should be arranged in two layers, each face down."

**CARL NORMAN POSTCARDS.**—Mr. Carl Norman, well known for years past as a landscape photographer, informs us that the agreement under which he has acted as manager of the Photochrom Company at Tunbridge Wells having come to an end, he has recommenced in business for himself at Barnet, London, N., as a printer of pictorial postcards. Mr. Norman sends us specimens of his work in collotype, P.O.P., and chromo cards, as well as of hand-coloured productions, all of which are excellent. Mr. Norman is evidently well able to compete in both quality and price with others in the public postcard trade.

## CATALOGUES AND TRADE NOTICES.

**CARBONOGRAPH.**—A new pamphlet of instruction in their new bromide-carbon process has been issued by the Rotary Photographic Company, Limited, Moorfields, E.C. It gives the directions for working the process in the simplest form.

**"OXTS" LENSES.**—Messrs. Aldis Bros., Old Grange Road, Spark-hill, Birmingham, have issued a circular of prices, which gives also a brief description of the properties of their new and moderately priced lenses.

**THE CURRENT NUMBER** of the "Prism," the miniature monthly issued by Messrs. A. E. Staley and Co. for the Bausch and Lomb Co., contains some readable notes on indoor portraiture. Messrs. Staley send the "Prism" on receipt of one penny stamp for postage.

**"THE PROFESSIONAL PHOTOGRAPHER,"** the monthly journal of the Kodak Co., contains in its current March issue some notes on rapid

photography with a "Graflex" reflector camera, on dry mounting, the working-up of enlargements, and two interesting notices of Mr. George Davison and the late Mr. Horsley Hinton.

A CIRCULAR from the Hales Camera Co., Bridgeton, New Jersey, U.S.A., gives us particulars of a full-size focussing camera in which no mirror is employed.

MESSRS. WALTER TYLER, LTD., of 48 to 50, Waterloo Road, London, S.E., have issued a comprehensive and abundantly illustrated list of the optical lanterns, cinematographs, and accessories which they are in a position to supply. From the same firm we have also received a catalogue of a large variety of lantern slides, which are available for hire or purchase, and which extend over a very wide range of subjects. Both lists should prove of interest to lecturers and other users of the lantern and cinematograph, and may be obtained on application to Messrs. Tyler at the above address.

MESSRS. TAYLOR, TAYLOR, AND HOBSON, in their 1908 catalogue, which is the 24th edition of their series of price lists, announce a reduction in prices of the Cooke lens, Series II., f/4.5 and Series IV., f/5.6. The list gives very full particulars of the various high-class lenses made by Messrs. Taylor, including those relating to the new wide-angle "Primoplano" Cooke. The table of conjugate foci is a useful feature of the list, and we are glad to see that the notes on a lens's action is included, as it gives a plain and eminently practical review for the guidance of a purchaser. The list also includes the specification of the lately introduced Taylor, Taylor, and Hobson focal-plane reflex. Messrs. Taylor, Taylor, and Hobson offer to send this handsomely printed and illustrated list post free on application.

MESSRS. REYNOLDS AND BRANSON, LTD., have issued an abridged list of their photographic specialties, amongst which we may make special mention of the series of "Rystos" dark-room lamps, including the new pattern of safety incandescent gas lamp, and also the "Rystos" sequential developing baths, which are made to take plates in both the English and Continental sizes, from 3½in. by 2½in. up to whole plate. Copies of the list may be obtained from Messrs. Reynolds and Branson, at 14, Commercial Street, Leeds.

 heim Club. Smoking Concert.

# ROYAL PHOTOGRAPHIC SOCIETY.

ETING held March 31, Mr. J. C. S. Mummery in the chair. Mr. Bickerton, F.Z.S., gave a lecture on "The Camera as an Aid to Study of Birds," illustrating his remarks by a large number of term slides, which created much interest amongst his audience.

THE UNITED STEREOSCOPIC SOCIETY held a meeting for its London suburban members on March 28 at Shepherd's Bush, when Mr. Brooker entertained the gathering with an illustrated lecture on photographic work in the neighbourhood of Rye and Winchelsea. As society is organising an excursion to this district at Easter the lure was singularly appropriate. After the lecture Mr. A. J. Low, secretary, presented souvenirs in the form of booklets, containing copies of the winning prints of the year, to Mrs. Owen and Victor Selb.

SOUTHAMPTON CAMERA CLUB.—On Monday, March 23, two lantern competitions were held, at which Mr. O. P. Butler and Mr. Daw were adjudged the winners. Mr. S. G. Kimber judged entries, and at the conclusion gave a helpful criticism to each of competing slides.

ROYDON CAMERA CLUB.—The president (Mr. J. M. Sellors) gave demonstration on enlarging with home-made apparatus. It has in the practice of this year's president when he requires such appliances as reflex and other cameras, enlarging lanterns, and so forth, to design and make them for himself, and thoroughly satisfactory tools they invariably turn out to be. Up to the present it is believed he has drawn the line at manufacturing such things as stigmatic lenses and dry plates, and has even been known to purchase printing papers on occasion. On Wednesday, the 18th ult., slide papers were very much in evidence, the excellent products Messrs. Ilford, Illingworth, Kodak, and Wellington and Ward being in turn requisitioned for the production of a number of capital effect and "combination" enlargements. A home-made swinging stand for rendering converging lines parallel was also shown, the consequent distortion produced by the elongation, or compression of such lines, apparently, being considered of no moment from the "artistic" standpoint. A suggestion by a member that the method might advantageously be employed in portraiture for lengthening out wide-angle lenses of the horizontal type failed to meet with the appreciation its doubtful potentialities deserved. A free distribution during the evening of sample packets of Messrs. Wellington and Ward's bromide prints afforded a "grateful and comforting" touch to a most interesting and instructive demonstration.

LONDON PHOTOGRAPHIC SOCIETY.—At the annual general meeting held recently the following officers were elected:—President, F. C. Boys; vice-president, H. W. Bennett, F.R.P.S.; hon. treasurer, Farrow; hon. lanternist and librarian, W. Hornby; hon. secretary, Donald S. Parsons, 119, Kingston Road, Ilford; hon. assistant secretary, H. Eales; committee: Messrs. Goodchild, Haslam, Lyddon, Perrett, Schofield, Weaver, Westlorton, Whitelaw.

PROPOSED PHOTOGRAPHIC SOCIETY FOR HAWICK.—At a well-attended meeting last week, at which Mr. T. G. Winning presided, was resolved to take steps towards the formation of a photographic society for Hawick, a committee being appointed to obtain names of intending members and report thereon.

BROMLEY CAMERA CLUB.—An exhibition under the auspices of the above club will be held in the School of Science and Art, Bromley, Kent, from June 10 to 12, inclusive. There will be three open classes, in which silver and bronze medals will be placed at the disposal of the judge, Mr. Furley Lewis, F.R.P.S. A special silver medal will be awarded to the best picture in the members' classes, and a special gold medal to the best picture in the exhibition. Entries close June 1. Entry forms are now ready, and may be obtained from the hon. sec., Mr. Thomas D. Gratz, "Collingtree," Cambridge Road, Bromley, Kent.

## Commercial & Legal Intelligence.

AT STAMFORD HILL BANKRUPTCY.—At the London Bankruptcy Court last week the first meeting of creditors was held under the failure of Solomon Wolson, described as a photographer, of 126, Homeleigh Road, Stamford Hill. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £868 11s. 10d., of which £820 11s. 10d. was due to unsecured creditors. The assets consisted of bad debts £447, estimated to be of no realisable value. It appeared that the debtor came to this country some fourteen years ago, and for seven years was engaged as a photographer. He then went to Russia for 3½ years, and returned to this country at the expiration of that period with a capital of £30. He then commenced business in the diamond trade as a diamond broker. He used to earn from £6 to £8 per week. He had no office of his own, but used the Diamond Club, 82 Hatton Garden, E.C. He gave up this business in August last. Since September last he has been engaged as a photographer. The estate was left in the hands of the Official Receiver for summary administration in the usual manner.

BIRMINGHAM MANUFACTURER'S FAILURE.—At the Birmingham Official Receiver's Office on Monday, the first meeting took place of the creditors of Mr. John Page Croft, of Packwood, Grove Avenue, Moseley, carrying on business at Cooksey Road, Small Heath, as a photographic paper and apparatus maker, and also at 24, Quadrant Chambers, New Street, as a tea merchant, and Mr. Alfred Roffey, grocer, of 586, Coventry Road, Small Heath, who was a partner with Mr. Croft in the photographic business. The Assistant Official Receiver (Mr. Acheson) said that the statement of affairs showed that the unsecured liabilities of the photographic business amounted to £431 12s. 1d., the net assets totalled £125, and there was a deficiency of £306. During the past year, it appeared, there had been a loss on the business of £1,291, although neither debtor had drawn anything out. The assets would not realise as much as the debtors had estimated, for few of the book debts appeared to be recoverable. If they had attended to their respective businesses, instead of experimenting in photographic materials, they would probably not have come into the Bankruptcy Court. The photographic business was launched by Mr. Croft, Mr. Roffey joining him in 1906, the former putting £800 into the concern and the latter £250. No proper books had been kept, but they would be called upon to prepare accounts showing how the loss of £1,200 was made. Mr. Croft's private accounts showed liabilities amounting to £2,323, of which £1,065 was for money borrowed in April and May, 1907. Mr. Kimpton, solicitor, who appeared in the interests of Mr. Croft, said that the assets of the firm included a formula for a secret process, which, if perfected, would undoubtedly become very valuable. At present it had no market value, but progress was still being made with the experiments. The Official Receiver remains as trustee.

FIVE PHOTOGRAPHS FOR 2d.—William Allen was charged, at the Bristol Police Court last week, with obtaining by false pretences 2d. from Florence Bryant; 2d. from Elizabeth Sarah Groom; 3d. from Elizabeth Bowman; and 2d. from Lily Portch. Mrs. Bryant said that on March 7 the defendant called at her home, and asked her if she wanted the children photographed on postcards. He said he represented a firm of Park Street photographers, and arranged to make five photographs for 2d. This money he insisted upon having in advance, and gave receipts. Other witnesses, all living in the neighbourhood of Lincoln Street, Barton Hill, gave similar evidence. Detective Wallace said he made inquiries on Tuesday, and at a lodging-house in Gloucester Lane he saw the defendant at a table with a number of small pieces of paper, printing the words, "The Art Portrait Company, Park Street," on them with a copying-ink pencil. He took him into custody. Witness found there was no firm known as the Art Portrait Company in Park Street, and no firm of photographers who had employed the defendant. He had no photographic apparatus, but merely some specimen photographs. The defendant pleaded guilty and said he was out of work. The defendant said he came from Liverpool. The magistrates sent him to prison for three months, with hard labour.

BOGUS PHOTOGRAPHER.—Before Sheriff-Substitute Smith, at Selkirk, last week, a smart-looking young man, named George Wood, photographer, 1, Park Street, Galashiels, pleaded guilty to a series

of frauds, numbering about thirty, by taking, or pretending to take, photographs of various persons in the district. He received payment, amounting to over £2, which he appropriated, and failed to deliver the photographs.

The Procurator-Fiscal said there had been one hundred charges against accused, but seventy had been withdrawn.

Accused, in pleading for leniency, stated that he had just been released from a term of six weeks' imprisonment for a similar offence.

In sentencing Wood to fourteen days' imprisonment, his Lordship stated that he had taken into account his previous term of imprisonment.

#### NEW COMPANIES.

WM. HOPWOOD AND CO., LTD.—Registered March 19. Capital £2,000, in £1 shares. Objects: To carry on the business of wood, photo, and colour engravers, designers, photographers, general illustrators, electrotypers, and stereotypers; to acquire from H. Makinson and W. Hopwood an invention for improvements in producing and copying drawings, and to adopt an agreement between the said vendors of the first part, J. R. Burton and H. B. Burton of the second part, and C. Eyre (for the company) of the third part. No initial public issue. The first directors (to number not less than two nor more than seven) are: W. Hopwood, J. R. Burton, and H. B. Burton (life directors), H. Makinson, and J. L. Baldwin. Qualification of life directors, £250; of other directors, £100. Registered office, 32, Barton Arcade, Manchester.

CROWLEY KENDRICK AND CO., LIMITED.—Capital £7,000, in £1 shares (2,000 5 per cent. preference). Objects: To carry on the business of general merchants, factors, traders, exporters, importers, purveyors, contractors, dealers in foods, ores, minerals, and photographic films and apparatus, advertising and general agents, bankers, financiers, etc. No initial public issue.

## News and Notes.

ERRATUM.—We regret that in our notice of the "Multi-Screen," on page 251 of our last week's issue, Mr. E. Webster's number was wrongly given. This should be 161, High Holborn, not 101, as stated.

SOUTH LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.—We are asked to announce that by special request of the Borough Arts Committee the above exhibition will remain open up to to-morrow, April 4.

THE "PHOTO-SECESSION."—An exhibition of photographs by Mr. Eduard J. Steichen, including a number of Autochromes, was held at the little galleries of the "Photo-secession," from March 12 to April 2. The next exhibition will consist of a collection of drawings, lithographs, and water colours by Henry Matisse, the leader of the new movement in Paris, as represented in the Salon d'Automne.

MR WM. A. CASSON, barrister-at-law, who is a member of the London County Council and of the Royal Photographic Society, has been appointed to be a member of the committee of the London School of Photo-engraving and Lithography, Bolt Court, Fleet Street.

ROYAL PHOTOGRAPHIC SOCIETY.—It has been decided to make some alteration in the hours during which the society's house is open to members, which, after March 31, will be as follows: Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays from 10 a.m. till 10 p.m., and on Saturdays from 10 a.m. till 2 p.m.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.—The annual dinner was held on Saturday last at the Hotel Florence, instead of at the Holborn Restaurant, as hitherto. The innovation had much to recommend it, and as much, we think, to make the change regretted. Another new departure was the abolition of that social convention, evening dress. Whether from these causes or not, the function was one of the liveliest and most enjoyable in the annals of the society. All the speeches were greeted with hearty laughter, except where references were made to recent sad events. Owing to the indisposi-

tion of Mr. G. E. Brown, the first toast, that of "The N.M.P.S.," was given by Mr. F. C. Tilney. Mr. Louis Dick toasted the judges, and Mr. Mummary, Pres.R.P.S., responded and presented certificates. The toast of "The Photographic Press" was given by Mr. Cauldwell, and was responded to by Mr. Wastell in his inimitable manner. "The Visitors" fell to Mr. H. Stuart, and was answered by Mr. E. T. Holding. A feature of the evening was the presentation of field glasses to the retiring president (Mr. H. Stuart), whose reception of the testimonial was a perfect model of matter and manner in public speaking. An enjoyable entertainment was interspersed, the best appreciated items of which were the musical sketches of Mr. Archie Naish, a pianist who can make a Bach fugue out of "La Maxisse" and an imitation "1812" overture out of the "Russian National Anthem" and "The Marseillaise," in counterpoint.

FIRE IN A LARBERT STUDIO.—Last week a fire was discovered to have broken out in the studio at Allanbank, Larbert, occupied by Fred Murray, photographer. The building, which was of wood, and not immediately attached to any dwelling, was entirely burned to the ground, including the whole stock of valuable negatives, framed pictures, etc. The damage, which is estimated at about £250, is partly covered by insurance.

THE LONDON COUNTY COUNCIL, at the meeting on Tuesday, agreed to give permission to the promoters of the Franco-British Exhibition to make a number of cinematograph and stereoscopic illustrations of work and other occupations in connection with school and college life for display at the exhibition.

PHOTOGRAPHY IN SHIPPING ADVERTISEMENT.—The Cunard Steamship Company have issued an ingenious pocket-folder, showing a series of photographic pictures of the "Mauretania" in mid-ocean snapped from the Cunarder "Ivernia."

MR. J. LIZARS announces that he has taken additional business accommodation in Edinburgh at 15, Shandwick Place, adjoining his present premises at No. 13. A special feature will be the exhibition of examples of the work of all the best lenses, cameras, and printing processes. Purchasers can thus see at a glance what will best suit their individual requirements.

KENTMERE, LTD.—With a view to the better protection of their trade mark, "Kentmere," it was unanimously decided, at a special meeting of the shareholders of the Commercial Photo Company, Ltd., to alter the title of the firm to that of Kentmere, Ltd., and the alteration has now been duly authorised.

CHANGE OF ADDRESS.—Mr. Wm. Brooks, who for the past three and a half years has been at Laurel Villa, Wray Park, Reigate, has removed to 10, Richmond Road, Ilford, Essex, where he will still carry on his collodio-emulsion work, in which he has been engaged for many years past.

THE ROYAL INSTITUTE OF PAINTERS IN WATER COLOURS.—The present exhibition of this society numbers some sincere and interesting works among its ranks, but, on the whole, it cannot be said to be an improvement upon the show of last spring. There is an obvious attempt to display works which appeal to a low stratum of popular taste. The moral of such a fact is that the people with the best taste are not the best buyers. We think it a pity, nevertheless, that this society, boasting a Royal charter and handsome premises, cannot see their way to selecting more works of a sort that would improve the reputation of their exhibitions. Tom Browne's drolleries, for example, are more fit for the Burlington Arcade than for the R.I. We are glad to note two pictures here, by our own contributor and critic, Mr. F. C. Tilney.

CINEMATOGRAH REGULATIONS IN MIDDLESEX.—At the meeting, on March 26, of the Middlesex County Council, the Licensing Committee reported having made considerable alterations in the regulations governing the use of cinematographs, with a view to minimising to the utmost any possibility of danger arising from the use of these apparatus. The new regulations, which number twenty, provide that six days' notice must be given of any intended exhibition so that the Surveyor of the County Council may inspect the

apparatus and see it at work. The cinematograph must stand in a proof enclosure or room, the floor of which must be covered with asbestos sheeting. The door shall open outward, and shall be self-closing, and of the three windows necessary in front of the enclosure, the central one shall not exceed 8 in. square, and the windows on each side shall not exceed 6 in. square. A flap screen shall be provided over the three windows and made so as to be operated from both inside and outside the enclosure. A fireman or other capable person shall always be in attendance near the apparatus with a wet blanket, two buckets of water, and a box of sand shall be provided. The Licensing Committee may, in special circumstances and on the certificate of the county engineer and surveyor, modify any of the regulations or require the adoption of further precautions.

Dr. E. KONIG, of Meister Lucius and Brünig, is now engaged on the writing of a work on the modern screen-plate processes of photography, which will be issued shortly by Messrs. Gustav Schmidt, of Berlin, under the title "Die Autochrom-Photographie des Verwandten Dreifarbenraster-Verfahren." ("The Autochrome and Allied Three-colour-screen Process").

### PROFESSOR LIPPMANN'S STEREOSCOPIC PHOTOGRAPHS.

To the Editors.

Gentlemen,—Will you kindly allow me to answer a remark made in your issue of March 20? "Ex Cathedra" remarks that if the spectator views one of my relief-plates from a point where some material point of the landscape was located, that point alone is seen. It is and so it ought to be. The relief-plate shows the landscape just as it would be seen from the same viewing point, and this is the case even in this particular choice of a viewing point. Suppose that while looking at the real landscape the spectator brings his right eye gradually nearer to some material point, say a small projecting berry, he will see that berry, under an increasing angle, filling out larger and larger until it fills the field of view and shuts out the world. The net result of trying to peep at the landscape through a single berry is obvious. The same holds for the left eye. If that is illustrated by a leaflet, while its companion is hidden behind a berry, the berry can be seen at length but these two obtruding objects. The landscapes seen while looking at the relief plate will be the same. The interesting remark made in "Ex Cathedra" is, therefore, a projection to my theory of the properties of the relief-plate, but a confirmation of it in a very special case.—Believe me, Gentlemen, truly,  
G. LIPPMANN.

Faculté des Sciences de l'Université de Paris, Laboratoire des Recherches (Physique) à la Sorbonne, Paris, March 27, 1908.

### DEVELOPMENT TANKS.

To the Editors.

Gentlemen,—We note in your issue of the 20th a letter from Mr. I. Thompson with reference to markings in tank development, wherein he suggests a certain pattern of tank which would obviate trouble.

We have pleasure in informing you and him that we have for some time been engaged on experiments with a view to evolving a perfect tank, and we shall shortly be placing this on the market, so arranged that the developer may be circulated, and so the things complained of avoided.—Yours faithfully,  
BOOTS CASH CHEMISTS, LTD.

31, Farringdon Road, London, E.C., March 21, 1908.

### PROFESSIONAL PHOTOGRAPHY.

To the Editors.

Gentlemen,—Permit one who photographed the great British public before retouching of the negative was ever dreamed of just a

little say in this matter. I believe the first examples of retouching of the negative saw daylight at an exhibition of the Photographic Society of Great Britain, some forty or so years ago, or was it during the exhibition of life-size heads taken direct for the Robert Crawshaw Prize of £50 (in which the writer took part)? These examples were sent by the Chevalier Lafosse, of Manchester, and so puzzled the judges that they took the prints out of the frames to sponge them to find out whether they were worked-up prints or not. There is much temptation to enter into the wordy warfare *re* the criticism of Mr. F. C. Tilney, of the recent Exhibition of Professional Photography. I refrain from joining "the nest of hornets," but surely that definition is a mere figure of speech on Mr. Tilney's part. I come at once to the question: Why do we retouch? The exigencies of the principle of making pictures by light and chemical action compels it. For example, say, you have a lady sitter with a perfect complexion of health, clear and pearly. Her cheeks glow with the ruddy colour of perfect health. There you have the germ of the necessity for retouching, because that rosy glow of health will be rendered on the negative as a more or less dark patch. The lead pencil comes to our aid and restores the balance and makes the monotone of the cheeks, forehead, and throat harmonious and equal. This principle can be applied throughout the whole gamut of light and shade, of which a photographic picture is built. And now to quote Mr. Tilney as follows:—"If all is satisfactory before exposure is made it is madness to make graphic alterations of the resulting image."

But all is not satisfactory. The lady's complexion should be of a uniform marble whiteness, or the deathly pallor of illness to suit the chromatic capabilities of the photographic emulsion.—Yours faithfully,  
W. BARRY.

The Studios, 7 and 8, Park Street, Hull.

### MR. PONTING'S PHOTOGRAPHS OF THE ORIENT.

To the Editors.

Gentlemen,—May I correct a little error in Mr. Tilney's review of my photographs in your issue of the 20th inst.?

He speaks of the Great Wall of China as "seen to be low enough to allow a native to lean over."

I would point out that the photograph is made from the top of the wall, which is at this point about twenty-five feet high and fifteen feet wide. The outer side of the old structure is embrasured, and high enough above the footway on the wall to screen the troops who might be defending it.

On the inner side there is merely a low parapet for the safety of those on top, and it is over this the native referred to is leaning.

Mr. Tilney's remark, however, although in error with regard to this particular picture, is by no means anomalous, as in the Lias Si mountains—the first range over which the ancient fortification runs after starting on its 2,000 miles and more of meandering—just north of Shan-hai-Kwan on the Gulf of Pechili, I found it low enough on top of some of the most inaccessible peaks to allow me easily to vault over.

The view of the wall shown was made where it crosses the Nankow Pass, about fifty miles north of Peking, and this result was obtained only after spending three days and nights in a poor Chinese country inn, waiting for the haze to pass away.

As Mr. Tilney appears to be uncertain as to whether the title of No. 5, "O Tsuné San," is the lady's name, let me disperse all shadow of doubt in the matter by saying that it is, and that the interpretation thereof into English is "Honourable Miss Constancy." "O" is the honorific prefix always given to ladies' names in Japan, which usually are of flowers or virtues, though sometimes of fruits, birds, trees, or physical features of the land.

San means either Mr., Mrs., or Miss, but the honorific is only used for ladies. (San also means mountain.)

As O Tsuné San is a very well-known little lady indeed to almost every visitor to Miyanoshta, for she is the prosperous proprietor of a fine curio and picture shop, and as I know of at least three people who have been to see these pictures who know her personally, I would point out that the lady in No. 21, displaying her wealth of magnificent black hair, is not O Tsuné, but O Matsu San (Honourable Miss Pine Tree), a friend of the former, and equally charming.

The use of the "O" in a possible vocative sense, however, in the case of either of these dainty maids, may well describe me, or anyone

else's, feeling, for never have I had more gentle, courteous, obliging, and altogether delightful models.

I thank Mr. Tilney for his compliment to my portrait of her, but no photographer or painter could ever hope to portray the real charm of O Tsuné San or any other Japanese lady, any more than he could show the real beauty of Fuji San.—Yours very truly,

H. G. PONTING.

### THE PORTRAIT POSTCARD.

To the Editors.

Gentlemen,—I have read with interest the letter of "Postcard" in your last issue, and, like him, have suffered much by this pernicious innovation.

It is very well for some people to say "go in for it strong and make money," but when one is settled in a little town of about 3,000, which at fair prices would just provide enough business to make a comfortable living, what would the nett amount be if we did postcards ad lib. at 2s. 6d. per dozen? It would simply make death welcome at any moment.

My attitude towards this thing is as follows:—When a customer comes in for postcards I spend considerable time in explaining to him (or her) that although popular, postcards are by no manner of means the high class of work which he (or she) would like, and that they are hastily produced in cheap material, and that I don't care a hang whether they fade next week or not.

This generally makes them think it is better to spend a little more and have work that I guarantee.

If they will have postcards my price is 3s. 6d. per dozen, and I will not do them for less and give a proof. I spend very little time in retouching, and never exhibit a postcard in my showcase.

As it is, my receipts have dropped 25 per cent. during the last three or four years, although the amount of work has increased.

What with landscape postcards as well, I have to work several hours a day more than I used to—for less money in the aggregate.

I smiled when reading those letters in the JOURNAL some weeks ago, by the gentleman who wanted photography placed on similar pedestals to medicine and law. Did he properly consider the matter? Did he consider how the country is overrun by postcard fiends and enlargement vampires, many of whom could scarcely spell correctly the names of the goods they hawk, whose only hope or care is to cut the price down to the last farthing—offering to do postcards in this town for 1s. 6d. per dozen, or 1s. the half dozen?

Is this the art-science to be ennobled? I throw not. But is there any remedy? It is doubtful. Certainly not by competitive examinations and diplomas. My idea to improve matters would be to place photographers on the same basis as auctioneers and appraisers, and to make every person taking photographs for gain to pay £10 per annum for a licence, and this licence to be only valid in the town or district council area that it is taken out for.

This would benefit the revenue of the country, and at the same time clip the wings of those vultures who swarm the country to batten on the provender which properly belongs to another. Will the Professional Photographic Association stir?—Yours faithfully,

March 27, 1908. FAIR TRADE AND FAIR PRICES.

To the Editors.

Gentlemen,—I read with much interest the letter of "Postcard" last week, and was glad the subject of portrait postcards was being ventilated. It is a problem that has been perplexing me for some months, and I held back as long as possible before showing them, but at last a man opened against me with postcards at 2s. 6d. dozen. I was then obliged to enter into competition. I obtain 3s. 6d. dozen, but in a small town such as I live in there is not sufficient scope to do a large enough business to get any return. In consequence of postcards we get infinitely more work than formerly, and not half so much money, consequently one cannot reduce the staff.

Some of my clients have a dozen postcards, others bring them back to be mounted; well, we ask 6d. each, and use a 10 x 8 mount, then the finished picture has every appearance of panel cabinets at 18s. dozen. In many cases we cannot get 6d. for mounting.

This style of portraiture is come, and is going to stop, and what are we as photographers going to do? We have to use a half-plate, retouch the negative, and print twelve copies for 3s. 6d. I do not submit proofs, but in no case do I turn out the cards unless they are

good. I shall await with interest the result of this correspondence and remain, yours, etc.,

PROFESSIONAL.

To the Editors.

Gentlemen,—Referring to "Postcard's" letter, it seems to me the only way in which a photographer in good position who undertakes portrait postcards can meet the difficult question of price is to fix a charge for making the negative. It is all very well to print photo-postcards of views from stock negatives at 2s. per dozen, but to include the making a negative (no doubt retouching and proofs, and second sitting if not approved, would be required) in a charge of 2s. 6d. per dozen for postcard portraits is an absurd killing of the portrait trade.—Yours truly,

A COUNTRY PHOTOGRAPHER.

March 30, 1908.

### FOGGING OF PLATES IN THE DARK.

To the Editors.

Gentlemen,—I still hear of photographic plates being spoiled especially in long expeditions, by being placed in proximity or contact with bodies which act in the dark on the photographic film. Low exposure and high temperature increases this action to a great extent. Among substances commonly used in photographic apparatus which have this property of acting on a photographic film, are wood, aluminium, straw-board, leather in its prepared state, and almost all varnishes. On the other hand, copper, ebonite, vulcanised fibre, paraffin wax, Bristol board, gum arabic, secotine, lampblack of good quality, do not act on a plate. Brass acts slightly, but it varies with its composition. The action of the aluminium is easily and effectually stopped by painting it over with a very dilute solution of platinum chloride. The action of wood is prevented at least to a very considerable extent by soaking it in melted paraffin, and removing the excess by a hot iron.

W. J. RUSSELL.

Davy-Faraday Laboratory, Royal Institution.

March 26, 1908.

### THE "TWO-EYED" LENS.

To the Editors.

Gentlemen,—As you condemn in such a free way this method of producing stereoscopic pairs, I wonder if you have seen some of the results. Enclosed are two, the first of a microscope and accessories; this was taken with a Zeiss "Unar" lens, that does in itself distort, and this result certainly shows no distortion whatever. I do not know what the "conditions" are that you mention as being necessary to produce a stereoscopic pair, but I judge by the result. This microscope group forms an easily combining, strong stereoscopic pair. I hope you will see your way to publish this, point out its defects, if you can find any. The other subject is from a microscopic slide, and is of mallow pollen, magnified about x 1,000. Is this defective? Where? Did you ever see two better stereoscopic pairs?

At the London and provincial demonstration I did show a distorted image, of some coins, done so intentionally, but as I explained that was produced by a totally different method.

As for the diffusion screen, that must be your own invention, mine. I put a perforated screen with fifty holes in it, in front of the lens, and showed that by that means we got on the screen different images of the one subject at the same time.

I said nothing about diffusion.

If these are not truly stereoscopic pairs, I shall be glad to know what are, and why these may not be.

If anyone specially interested in these things would care to see the original photographs and others in a stereoscope, I shall be pleased to show them at any time, 5 to 6 p.m. being most convenient, at my office.

A. E. SMITH.

8, Farringdon Avenue, London, E.C.4.

March 23, 1908.

[Our note did not condemn our correspondent's work; it simply pointed out that strange and unjustifiable conclusions had been drawn from it by others. Old experiments, such as the production of stereographs with eccentrically stopped lenses, are always interesting, and often well worth working through again. As to the specimens, it is next to impossible to test the truth of a stereoscopic pair by inspection in the stereoscope; the only way to be quite sure they are correct is to make and mount them on correct principles. If

stop was situated in the plane of the iris, the camera result is probably correct, but if the stops were in front of the lens the result is certain to be more or less out of drawing, seeing that photographic lenses are not corrected for distortion for such a position of stop. The extent of the error will vary with different lenses, and the amount of displacement from the proper position. In some it may give obviously wrong perspective, in others simply an appearance of exaggerated relief. We always find a lens with Water-stops most convenient for experiments such as these. Our correspondent's results are excellent photographs, but as stereographs show a suspiciously strong relief. Unfortunately they are made in a way that naturally exaggerates relief, the greater part of a subject standing out in front of the mount. No stereographs look quite natural when trimmed in this way, which is a well-known method of introducing an appearance of relief into a combination of two similar photographs. If the prints are trimmed by near instead of distant ones, this defect will disappear, and one can judge better whether the result is true or not. It is necessary to remember that strong relief is nearly always untrue. As to the subject, stereomicrographs may be described as combinations of elevations, therefore the effect differs from that of the combination of the two perfect perspectives, obtainable in the camera, and is quite natural nor truly stereoscopic. The eccentric stops are equally capable of giving as good results as any other method. Our correspondent's specimen is very much affected by the wrong trimming, and we would also point out that in the stereoscope the images are very markedly ellipsoidal, and are all situated with their long axis parallel. Our correspondent, as the photographer, can judge for himself as to whether this effect is correct or not. With regard to diffusion effect, this was suggested by one of his comments. We think it necessary, however, to point out that the multiplicity of images produced by a multiple stop depends entirely on the stop being out of focus. In fact, it is a good test for true focus, and we have frequently used during many years.—Eds.,

# “SYNOLOIDS,” LIMITED.

To the Editors.

Gentlemen,—As a result of the advertisement and the article which appeared in the previous issue of your paper, we have been inundated with inquiries, notwithstanding the fact that you mentioned in the head of the article that we should not be ready for a few days. We shall be greatly obliged if you will publish to your readers this explanation, with our assurance that every effort is being made to expedite the manufacture of our paper and developer, and that we are in a position to make deliveries within the next few days.—Yours faithfully,  
“SYNOLOIDS,” LIMITED.  
Trancechurch Street, London, E.C.

PHOTOGRAPHIC CONVENTION.—The writer who under the thin “Pilgrim” is now contributing to the American photographic papers has some interesting comments in the current issue of “The Photographer.” He says: “Of course, America is the original of the British Convention, the late Mr. J. Traill Taylor, who in this country in 1885, having seized upon the idea and taken it across the Atlantic, to crystallise it at Derby, England, in 1886, was the first British Convention was held. Of that Convention I have many pleasant and interesting experiences, not the least of which was that I had the honour of serving as president during the years 1900-1901. Only the other day I received from Mr. F. A. T. the hon. secretary of the Convention, a valuable souvenir of his presidency. This was the official badge I wore on assuming the office, and which I passed on to my successor, Sir William Herschel, the great astronomer Herschel, who presided in 1902. The Convention meetings make very agreeable reunions, being attended by both amateurs and professionals, and there is no better way of spending a short vacation in some old cathedral town amidst other and equally interesting historical surroundings than to do in an English summer. The every-day interests of a professional worker do not, however, figure on the programme as much as to do in the New York State and other conventions, and I think the last regard that I think the English professional photographer should take a leaf out of his American confrère's book.”

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to “THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C.” Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

W. Hampton, 195½, Argyle Street, Glasgow. Photograph of a Fine Example of a Bursting Wave in the Storm at Largs, February 22, 1908.  
Davis, Clements & Co., Frederic Street, Luton, Beds. Photograph of a Placed Group of Thirty-three Hats.  
G. F. Watson, Park Green Studio, Macclesfield, Cheshire. Photograph of Jas. Kershaw, Esq., of Macclesfield.  
H. Hilton, 8, George Street, Brighton. Photograph of the Brighton United Twins.

ACID SULPHITE, ETC.—(1) In the article in the current issue re enlarged negatives direct no strength is given for the bisulphite of soda solution in the bath for removing the chromium salts. Is this the “bisulphite lye” of Lumière? If so, I think I have read elsewhere that it can be practically substituted by a sulphite of soda solution, and, if so, it seems strange, as in the formula in question there is also some sulphite of soda. I would not ask the question only “bisulphite lye” is not readily obtainable, and I would like to make it up myself if I can get the constituents. (2) I have a half-plate enlarger with a lens by Clements. It is fitted with Waterhouse diaphragm stops, and I find that no matter which stop is used I cannot get a clear disc. It is all right with full aperture, but as I use a Nernst lamp I want to cut the light down for thin negatives. The disc has violet and orange markings, particularly at the edges, when the stops are in. Shall be obliged if you can explain it.—F. C. (Bray).

(1) The sulphite has not the same effect as the bi-sulphite. You can obtain the latter from the Lumière Co., 89, Great Russell Street, London, W.C., or from F. C. Clarkson, Colchester. (2) If you cannot get good disc with small stops by readjusting the light it is clear that the aperture is too small to pass all the light. Very often it is impossible to get a clear disc if the lens is too small. You had better use full aperture and give short exposure with shutter, or else use slower bromide paper.

FACTORIES ACT.—I recently had the inspector of factory and workshops to see me, and amongst other questions he asked me what was the early closing day. I informed him we had no early closing day, as we only worked from 9 a.m. to 6 p.m., with one hour off for lunch (making forty-eight hours per week). 1. He says that I must let all women and young people under eighteen years of age, finish one specified day a week at four o'clock. Am I compelled to do this? 2. If so, does my receptionist come under this? (She is over twenty years of age). 3. Does a photographer come under the Factory and Workshop Act?—JUSTICE.

1. Yes; certainly you are. 2. The age makes no difference with females. If she takes no part in the working, such as mounting, spotting, and the like, but merely attends to the customers and correspondence, we imagine she would be classed as a shop hand, in which case the Factories Act would not apply to her. 3. Most decidedly he does. If you refer to our issue of September 13 of last year you will see an article on the Factory Act and photographers, which is very explanatory.

W. C. TIERNEY.—We advise you to write, mentioning this answer, to M. E. Husson, 207, Avenue de la Reine, Brussels.

HARRISON AND EVANS.—The address is 283, Regent Street, W.

PHOTOGRAPHIC PUZZLE.—Would you kindly give me your opinion of the enclosed postcard? You will perceive through the man's legs the letters are quite transparent; also on the shoulder you will see the letter G is to be seen quite distinct. For any information

respecting this photographic puzzle I shall feel greatly obliged. The photograph was taken in the afternoon of one day last week about 4.30, dull afternoon.—F. MALTHOUSE.

It is quite evident that the man moved during the exposure. The letters were recorded while he was moving, and his own figure was recorded while he stood still for a few moments. The effect is common in long exposures.

**BLINDS FOR STUDIO.**—Please give information regarding suitable curtains or blinds generally used in studios in order to get control in lighting. I would like a semi-transparent material which would stand well without fading. Where can I obtain some, and what price should I pay for a good quality material, and oblige?—J. E. R.

No very definite advice can be given, as the aspect of the studio is not mentioned. However, if it has a southern aspect darker curtains will be required than if it has a northern one. If the latter, buff or light blue would be good. If the former, a more or less dark green would be preferable. Suitable material can be had from any upholsterer. If you have the top blinds, as shown in the sketch, we should advise far less "sag" than is shown in it. In the issue of the JOURNAL, August 30 last, there is an article on the subject, with an illustration showing an arrangement of roof blinds, which is far better than as shown in your sketch.

**DEVELOPER—LENS QUERY.**—1. Will you please give me the best developer you know of for portraits taken by electric light, the resulting negatives to be used solely for bromide printing? 2. Also please tell me a simple method of finding the focus and working aperture of a portrait lens.—M. I.

1. The developer that is used for portraits taken by daylight will do equally well for those exposed by electric light. You cannot do better than follow the formula given for the plates you employ. Metol yields delicate negatives, which are suitable for bromide printing; you might give that a trial. Several formulæ are given on pp. 788-9 of the "Almanac." 2. Focus the image of an object, say a cabinet picture, the same size on the focussing screen. Then remove the lens from the camera and measure the distance from the object to the focussing screen. One-fourth of this distance is the focus of the lens. Then measure the aperture of the fixed diaphragm into the focus of the lens, and that will give you the  $f$  value. This method is not strictly accurate, but it is simple and accurate enough for all practical purposes.

**LENS QUERIES.**—Will you kindly, through the "British Journal," advise me which would be the best lens for 12" by 10 groups in studio 21 by 15, quickest, at a moderate price? Also a lens for cabinet and c.d.v. portraits?—NOVICE.

The studio is very short for professional work, more especially for taking groups in, if they are composed of many persons. You will require a lens that will include a large field in proportion to its focal length, such as one or other of the anastigmatic types of 12in. or 13in. focus. If you want the quickest lens of this class you will not get it at a very moderate price. Better get price-lists of the different makers. For full-length cabinet pictures 'n so short a studio you require a lens of about 9in. focus. Such a lens will do very well for three-quarter and bust portraits (c.d.v. size), but for full-lengths you will require one of still shorter focus.

**DIOPTRES.**—1. Combined bath or acetate and subsequent fixing. 2 and 3. We refer you to the article in the "B.J." for September 14, 1906, p. 725. See also the "Almanac," 1907, p. 775.

**REMOVING STAINS.**—Photographer's assistant would be greatly obliged if Editor can advise best method of removing stains developing pyro-ammonia? Hands much stained, therefore look bad in business. Have tried pumice.—T.

Rubbing with a few crystals of ammonium persulphate will often prove effective, but lemon juice is a slower and better remedy. You should keep your hands soft with some emollient, such as Hazeline, and they would not then stain so readily.

**E. R. BULLOCK.**—The best book we can refer you to is Duchochois's "Photographic Reproduction Processes," or Von Hübl's "Die Platinotypie." The latter is in German.

**RUSTON.**—Messrs. Agnew, 39B, Old Bond Street, London, W.; Messrs. Sotheby, 9 to 13, Wellington Street, Strand, London, W.C.; Messrs. Christie, Manson, and Co., 8, King Street, St. James, London, S.W.; Messrs. Goupil and Co., 25, Bedford Street, Strand, London, W.C.; Mr. Franz Hanfstaengl, 16, Pall

Mall East, London, S.W.; the Berlin Photographic Company, 133, New Bond Street, London, W.

**S. H. C.**—1 and 2. In both cases optical flats are used if specially ordered. A seven or ten times screen, with a panchromatic glass will be sufficient for paintings, and the lighter filter for landscape work. The make you name is excellent. 4. There are three of the screens; the third should be used for painting the first and second for landscapes. 5. Optical flats are preferable, as they do not impair the definition of the lens, and, if in front of the lens, require no adjustment for focus. Glass which is not perfectly flat may upset the definition.

**J. VAN DER RIGK.**—(1) Felix Schoeller, Burg. Greteesch, Osnabrück, Germany. (2) White shellac, 300 gms.; gum elemi, 30 gms.; Canada balsam, 50 gms.; methylated spirit, 1,000 ccs.

**MARKINGS ON PRINTS.**—I should be pleased if you could explain the marks on enclosed card. I used lead combined bath, but did not know marks until print was dry. I am in the habit of keeping the bath and adding stock solution for each toning, adding my gold to the bath.—W. W.

The print looks as if bath was nearly exhausted. The tone generally is uneven. But possibly the centre part was in contact with another print, and so the toning action was hindered. You do say if this is a solitary specimen of failure or one of a batch. If the former we should disregard it as an accident.

**L. MATHEW.**—There has been no treatise of late in English on the recovery of residues. We do not understand your query as to Spitta's book, but the publishers, Messrs. Iliffe, of Tudor Street, E.C., can give you every particular.

**G. H. B. and Others.**—In our next.

**PRINTER.**—Apparently the blotting-paper is the cause. It would be this effect if, as is the case with the cheaper qualities, it contained traces of hypo.

**WILKINSON.**—There is no plate or emulsion that will do what you want. We can only refer you to the developer for direct reversal containing thiocarbamide. General Waterhouse worked out the process some years ago, but it has never come into practical use. His formula was:—

A. Eikonogen, 5 parts; soda sulphite, 10 parts; water, 100 parts.

B. Soda carbonate cryst., 4 parts; water, 100 parts. C. Thiocarbamide, 1 part; water, 1,000 parts. Use A, 1 part; C, 1 part; B, 2 parts; and to every 100 parts of this mixture add  $\frac{1}{2}$  to 1 of 10 per cent. potass bromide solution.

**EAGER.**—This is a question that can only be answered as the result of practical experiment, and we are afraid your only course is to test the matter.

**LENS QUERY.**—I am in want of an anastigmat lens. A dealer's secondhand photographic apparatus has one by —, working at  $f/6.8$ , at just the focus that would suit me, but on examination I noticed several small specks in the glass, almost like bubbles. On calling the dealer's attention to them he said that all these new lenses had them, more or less, but they were of no consequence. Is that so?—T. R. CONWAY.

Yes, what the dealer told you is quite correct. With some of the new glasses it is impossible to manufacture entirely free from air bubbles, but the latter are of no practical consequence. If the lens is otherwise perfect you will be quite safe in purchasing it.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are taken absolutely without condition, expressed or implied, as to what appears on the text portion of the paper.

y for a trifle. (P. 278.)

## EX CATHEDRA.

### The Photographs of the Far East.

We would remind our readers that the exhibition of photographs of the Orient, by Mr. H. G. Ponting, now being held at the house of the "B.J." closes on Thursday next, April 16. In response to several requests from would-be visitors who find it impossible to reach Wellington Street during the hours the exhibition is open, we beg to announce that to-morrow, Saturday, April 11, the pictures will remain on view until 5 o'clock in the afternoon, which, it is hoped, will enable many who could not otherwise do so, to inspect this notable collection of photographic pictures.

\* \* \*

### The Horsley-Hinton Memorial Fund.

With many feelings of regret that such a course should be necessary, we open our columns this week to the announcement of a fund in memoriam of the late Horsley Hinton. Mr. Hinton, as the memorialists truly point out, gave liberally, even rashly, in response to appeals from friends and kinsfolk, and was often generous when he would have been just in holding his purse closed. However, we hope that the appeal which is now made will not fail in enlisting the sympathies of some of our readers.

\* \* \*

### The Society of Colour Photographers.

We would draw the attention of every reader actually practising any process of colour photography to the second annual exhibition of the Society of Colour Photography which takes place in June next. We give the official particulars in another column, but would further remind colour workers that no charge is made for wall space either for prints or transparencies, that no awards are given, and that all further particulars will be immediately supplied by the honorary secretary of the society, Mr. Henry J. Comley, of Surrey House, Stroud, Gloucestershire.

\* \* \*

### The Paris Photographic Salon.

The twelfth annual exhibition promoted by the Photo-Club de Paris, and known usually as the "Paris Photographic Salon," will be held in the Cercle Artistique et Littéraire, No. 7, Rue Volney, from May 15 to June 8. As in previous years, the aim of the exhibition is essentially artistic, and, as hitherto, there will be no charge for wall space, no medals, and no appeal from the decisions of the selecting committee appointed by the Photo-Club de Paris. Entry forms, obtainable from 44, Rue des Mathurins, Paris, must be returned to the Photo-Club at this address by April 15 at the latest. The prints themselves should be consigned to reach the same address by May 1.

### Colour in the Stereoscope.

Attention has several times been drawn to the fact that if we prepare two Autochromes of the same subject, reverse one only, and then make up the two similarly to a stereoscopic slide, examination of the combined image in the stereoscope shows a grey image only. The reversed and the non-reversed images are, of course, in complementary colours which neutralise each other when combined, but the question whether colours can be combined in the stereoscope in this way is one upon which there has been much difference of opinion. Du Tour experimented on the mental mixing of colours by binocular vision, and in his experiment as quoted by Wheatstone he attempted to produce green by combining blue and yellow, but failed. Wheatstone states that if blue is presented to one eye and red to the other no trace of violet is seen, nor do red and yellow combined in the same way produce orange. If, however, complementary colours neutralise each other as in the Autochrome experiment, then blue and yellow should produce green, and red and blue should produce, not violet, but purple. We have often repeated these experiments of Wheatstone, and the only conclusion we could arrive at was that he was quite wrong in his conclusions. The colours will combine in precisely the way that he says they do not. He states that we simply see the two colours, the one or the other alternately predominating either partially or wholly over the field, and that we never see the combination of the two. The effect that he describes is readily observed, but it only occurs when the union of the two images is imperfect. A little mental effort will combine the colours perfectly, but it is certainly rather remarkable that the result should apparently be subtractive and not additive. Blue and yellow make green, not grey; and red and green make a sage green, not a yellow. Possibly, however, these effects are only due to the colours being in wrong proportions, for additive results are the ones we should expect. Carefully adjusted colours are necessary to determine this point, but the important fact that the colours will combine is easily proved in spite of Wheatstone's statements.

\* \* \*

### The Playertype Process.

The death of Mr. J. Hort Player has reminded everyone of the Playertype process, but, though this process was only published for the first time in the "Photographic Journal" for November, 1904, its details have been forgotten by many photographers. From the practical point of view it could hardly be considered to be a process of importance, but, theoretically, it is interesting as an example of a method of copying that still requires explanation. Briefly, the process was as follows: A sheet of translucent paper coated with calcium sulphide was rendered luminous by an exposure of from ten to twenty seconds to daylight. The phosphorescent surface was then brought into contact with the positive print to be copied, the two being kept together by the pressure of a sheet of glass. It was next illuminated for from five to ten minutes by yellow light alone, such as that of a gas flame, the light being allowed to pass through the phosphorescent paper on to the original picture. After this the luminous sheet was removed from the print, pressed into contact with a sheet of rapid bromide paper, and then the two were heated to about 120 deg. F. for twenty to thirty minutes. The bromide paper was then developed and fixed in the usual way, and a bromide copy of the original resulted. As a rule the result obtained was not very sharp, for there seemed to be a spreading of the image; but precisely why and how the result was produced no one seemed quite able to determine. The process is still an interesting subject for experiment, and

possibly the principles involved may some day have more important application.

\* \* \*

**Sales of Daguerreotypes.** Daguerreotypes are very often looked upon as rare, much rarer than they really are, and the possessor of one or two daguerreotypes often thinks he holds a prize of great monetary value. A really good slide is certainly an object of great interest, and if cleaned it is often one of great beauty, for there is no other photographic process which gives such a realistic effect in the stereoscope. The slides may, therefore, be truly described as valuable, though, unfortunately, when their value is translated into cash in the sale room the owner is often disappointed. Only last week a set of nine dozen daguerreotype stereoscopic slides were sold at Mr. Stevens' auction rooms at the bargain price of twenty-five shillings, which was out at a very small fraction over 2½d. each. A good many were excellent specimens, and some very good examples of coloured slides were in the set, so that the purchaser may be considered to have made a very good bargain. Coloured daguerreotypes have a peculiar interest, for the best specimens the colouring is so delicate and skilfully applied that the result is something of a mystery to modern photographers. A very fine example of a coloured slide was shown at the R.P.S. last week by a member who had recently rescued it from a dust heap! In spite of their small cash value, we think daguerreotypes are well worth collecting and preserving, especially when they are in the form of stereoscope slides. Unfortunately the daguerreotype is generally associated with an insipid portrait of some unknown individual. Many of these are no more interesting than the old-time collodion positive glass, but the stereo slides very often represent interesting subjects and, moreover, give a quite unique effect in the stereoscope.

\* \* \*

### Daylight Saving.

The sudden demise of the Daylight Saving Bill recently introduced into the House of Commons has been greeted with grief by an esteemed contemporary, apparently because it would have afforded opportunities for the exposure of a greater number of photographic plates than can be consumed with the usual allowance of daylight. The Bill in question was a very original one, as it projected putting all clocks forward twenty minutes between the hours of two and three on each of the first four Sundays in April, and putting them back again by the same amount and at the same times on each of the first four Sundays in September. If this were done, we should gain something like 200 hours of daylight, and should, of course, be able to dispense with a proportionate extra number of plates; but we do not think many would think all this worth the candles consumed when prowling around the house at two a.m. in the morning to meddle with the clocks.

\* \* \*

### Ladies' Photographic Associations.

The photographic exhibition held by the "Berliner Women's Club," in Berlin, at present, is a pretty idea, capable of being extended further, and should prove a great success if it introduced into other towns. It is entirely a ladies' exhibition, since there is not a single example of work of the sterner sex shown on the walls. As becomes a ladies' exhibition, the majority of the exhibits are flower studies, pictures of children, and portraits. There are also some very good costume studies, especially of quaint dresses worn by peasants in some of the out-of-the-way districts of Germany. Interiors and decorative work such as appeals particularly to women are not wanted.

works of professional lady workers and amateurs are exhibited side by side, and bear striking testimony to the enthusiasm and knowledge which German ladies are applying to the art. The exhibition is open to the public, and success with which it has met more than justifies the confidence of the promoters.

## RECENT CHANGES IN THE ARTISTIC COPYRIGHT LAW OF GERMANY.

There seems to be some misunderstanding in this country concerning the recent changes which have been introduced into the German artistic copyright law, and many of those who have dealings with German publishers and clearing houses in that country are still doubtful if their interests are fully protected. We can assure them that they are as well protected in Germany as elsewhere. Fortunately for photographers and others interested in art objects, the old fiasco, which passed by the name of a law but was a law only in name, has been abolished after much agitation. The clause, "On an article of manufacture," which enabled anyone to reproduce a photograph often as he wished, despite the fact that it had previously been copyrighted, if he could only convince the authorities that it was reproduced on an "article of manufacture," has been entirely removed. It was behind this clause that postcard manufacturers sheltered themselves, without in any way infringing the law, flooded the market with millions of picture postcards of copyrighted photographs. This naturally gave rise to much bitterness, since it afforded neither artists nor photographers security in obtaining what was their just right, and, further, a continual source of loss to them. In this respect art was on the side of photography, since they had a common end in view. The pressure brought to bear on the authorities ultimately convinced them of the absurdity of a law which left one class of the community absolutely at the mercy of the other, and on January 9, 1907, the new law was passed and at once came into force. There has been a great outcry against it from the manufacturers of postcards, who, in consequence of the removal of the clause which enabled them to infringe any copyright with impunity, have lost what was their richest harvest. There is, however, no possibility of any alterations being made in the law as it stands at present. For the benefit of our readers having connections with Germany, we select a few of the principal points in the new law.

According to the new German artistic copyright law, any photograph is copyright, and this copyright

lasts for a period of ten years. No formalities, such as registration, or in any other way giving notice to the authorities, are necessary. It is advisable, as a means of avoiding possible complications, to print the name, address, and date of the appearance of the photograph, but the new law does not demand this as necessary, and clearly states that even without such information or precaution a photograph still enjoys the right of copyright, and for the period of ten years. In the event of anyone copying such a photograph, legal proceedings can at once be instituted against him. Should the offender be a postcard manufacturer he can be legally compelled to at once withdraw all cards or copies of the photographs prepared by him from sale. Damages can be claimed, and the amount of these latter is based on the loss suffered by the holder of the copyright on the sale of the original through its having been produced as a postcard; also upon the value of the original photograph.

The copyright of a photograph belongs to that person, or persons, to whose order it has been made. This clause may possibly give rise to some cause for dispute, but, as we understand the reading of the clause, it is applied in Germany exactly in the same way that it is applied with us. That is to say, if the photographer makes the photograph to the order of another party he has no right to produce any copies of the photograph, except by the order of that party or by his permission. Any breach of this clause is punishable. But if the photographer invites the party to sit to him, or can otherwise prove that he has not made the photograph to the order of another person, or by order, then the copyright is his alone, to do with it as he pleases.

In most points the law is practically the same as our own, and need not be gone into here. The principal point is, as we have already made clear, that photographs and art productions are, under the new law, protected in Germany, and the cost of prosecuting anyone breaking this law in Germany practically amounts to nothing when the prosecutor has a case against the defender. Since Germany is included in the Berne Convention, the same protection is given equally to all countries within the union, and, in accordance with the provisions of the Berne Convention, all that is necessary to secure copyright in Germany or other foreign country is that the legal formalities of the country in which the photographer resides (*i.e.*, "the country of origin") should be observed. We need only add that the ten years' copyright limit is reckoned from the year of publication, by publication being meant the giving out or making public of the photograph.

## THE HINTON MEMORIAL FUND.

WIDESPREAD desire has been expressed that there should be public recognition of the invaluable services rendered by late Alfred Horsley Hinton to the cause of photography. It appears to be a very practical way of showing such recognition. Though Mr. Hinton had been in an important position some years, he was entirely a self-made man, inheriting no property. Further, he responded liberally (perhaps even unjustly) to many family and other calls upon his purse. As a result of this—to our painful surprise—we find that the widow quite inadequately provided for, and in proposing to inaugurate a fund for her benefit we feel sure of the hearty support and cooperation of many readers of "The British Journal of Photography" and others interested in Mr. Hinton's work. The undersigned have formed themselves into a committee for

this purpose, and trust that this appeal may meet with a liberal response. Messrs. Hazell, Watson and Viney, Ltd., proprietors of "The Amateur Photographer," have most generously headed the list with an amount of 200 guineas. Subscriptions—no matter how small—will be gladly welcomed, and should be forwarded to Mr. Reginald Craigie, Hon. Treasurer, Horsley Hinton Memorial Fund, 52, Long Acre, London.

## THE DONISTHORPE PROCESS OF PRINTING WITHOUT LIGHT.

SINCE the appearance of the note on this printing method in the "B.J." of March 27 I have been able to put the process to some practical tests, and as the results will probably be useful to others trying it for the first time, I give my experiences in a fairly complete form. Described briefly, the process is as follows:—A negative is treated for five minutes with a toning solution containing vanadium, the result being a strongly-coloured negative image. At first it is a very blue green, but after washing for about five to ten minutes it is a brilliant green approaching emerald in colour, and at this stage it will be found that the negative image is in strong intaglio. After five minutes' immersion in a dye solution the plate is rinsed and a piece of gelatinized paper that has been soaked in water for a few minutes is squeegeed on to the film. In another five minutes or so this paper is stripped off, and a positive image in the colour of the dye is found to be impressed upon the gelatine surface. Success depends on two important factors: the condition of the toning solution and the quality of the negative. My first experiment completely failed through ignorance of the right conditions, so it is rather important to bear them carefully in mind.

First we can consider the toning solution. This is made up by mixing equal parts of two stock solutions supplied by the patentees, and it is imperative that both stock bottles should be kept quite in the dark. The toning operation may be carried out in the light, but the solution should only be mixed immediately before use and the stock bottles should then immediately be replaced in either a box or dark cupboard. Again, the mixed solution should not be used for more than two plates. It will tone quite a number of plates, but a sufficient hardening effect is not produced after the first two. If used for more than two, then the third plate will not be likely to print well, while the fourth will give nothing but a uselessly flat result. I am inclined to think that the solution works a little longer when used by artificial light than it does when daylight is employed, but this point is uncertain. In any case, I never found it safe to treat more than two plates with the same solution. The toning solution should remain quite clear during use. If it precipitates it is useless, and this effect will occur readily if the stock bottles have been exposed for any time to daylight. If the solution keep clean the first two plates can be relied on to work well, provided they are the right kind of negatives, and the quality of the negative is the next point to consider.

### The Negative.

A negative of a somewhat peculiar type is required for the process. The patentees describe it as a thin clear negative, with whites as clear as in a bromide print. The "whites," of course, are the deep shadows, and my tests show that these should be as nearly as possible of the "clear glass" variety, while the high-lights must only be of medium density. A very little veil or fog in the shadows is detrimental, and the amount we ordinarily expect in the usual negative made on a fast plate is fatal to the result. My most successful negatives were all modern slow plates, the best of all being on transparency plates. Messrs. Donisthorpe specially recommend metol, or amidol, as the developers that give the best results; but, as a matter of fact, I have not found the developer to be a factor of very much importance. The non-staining pyro soda developer, described in the "B.J." last year, proved very suitable, and fairly good results were also obtained with hydroquinone. This developer gives the right kind of shadow detail readily, but its tendency to produce very dense lights is rather against it for this particular process. Rodinal, 1 in 20, with two grains of bromide per ounce, works very well if the exposure is about right, and in my opinion more depends on the exposure

than on the developer. A "correct" exposure and short development is no doubt the thing to aim at, and in the case of a subject with great contrast a very light filter-screen to cut down the lights might be of advantage. Clean-working backed plates are, of course, necessary.

### Dyeing the Plate.

There is not much to be said about the dyeing, with the exception that some negatives require a longer immersion than others. A little veil in shadows or a little too much density in the light will prolong the first dyeing very greatly. When one print has been made, two or three minutes in the dye before making the next print is quite sufficient, as a rule. It is stated that the negative is sufficiently dyed when it looks like a positive against the light. This is a fairly good test, but I would add that the deepest shadows should be very dark indeed. Unsuitable negatives lead to all kinds of trouble in the dyeing, the high-lights are not dense enough they will absorb so much dye as to give a very flat result. If too dense the lighter tones will not take up any dye at all, and the result will be deficient in these tones. If the shadows are fogged or veiled, full depth of dye will not be taken up by them until the light have absorbed too much, and here again a flat result is produced. If the veil is at all dense the shadows will never take up enough dye.

All these experiments have been conducted on the usual type of photographic plate, fast and slow negative plates, and transparency plates; but Messrs. Donisthorpe promise a new special emulsion coated on black paper, and no doubt with an emulsion specially designed for the process the difficulty of securing negatives with clear shadows will disappear.

### The Printing Paper.

Among the gelatine papers used there was one specially prepared by the patentees which worked excellently, and gave an effect closely corresponding to glossy P.O.P. Fixed and wash P.O.P. papers work just as well, and matt varieties can be used in the same manner as the glossy. Carbon transfer and pigment papers I also tried with success. In fact, almost any kind of gelatinized paper seems to be serviceable provided it is not too rough. A rough paper could be squeegeed into contact with a glossy negative, and the result is therefore very spotty. The dyed image on the rough paper is, however, capable of very pleasing effects, and probably such paper can be used successfully with flexible paper negatives.

### Drying the Prints.

The inventors lay stress on the importance of drying the prints quickly. If the wet print is hung up to dry the dye tends to spread slightly, and so to give slightly blurred outlines. I found the best remedy was to blot the print immediately on removing it from the negative. Messrs. Donisthorpe advise dipping the prints into spirit before blotting, but this led to trouble in my case. It seems that the dye used is a mixture of several, including red and blue. The red appears to be rather readily soluble in the alcohol bath, and whenever I used such a bath a distinct bluish tint appeared in the half-tones. The result was an unpleasant double-tone effect that I avoided altogether by omitting the spirit bath.

The following is a brief epitome of the working instructions given by the inventors, very slightly modified in accordance with my experiences:—

Slightly under-develop the negative, stopping development while the whites still show quite clear.

Fix and wash very thoroughly, making sure that all hypodermic is eliminated, and dry the negative before proceeding further.

for five minutes in the toning and hardening solution, wash for ten minutes in cold water, wiping the surface of plate with cotton-wool to remove any sediment left by the g solution.

t in the dye-bath for from five to about ten minutes, or the negative, on being examined against white light, shows long positive image in the colour of the dye upon a green ed. The time for the first dyeing varies with the negative he dye used, and also with the temperature of the solutions. times half an hour's dyeing may be required.

use the dyed negative in cold water, wiping the surface with n-wool. This takes about a minute.

e gelatine paper should be soaked in water for about three tes or less in the case of a negative that has already had s made from it, while a longer soaking is desirable if the ive has not previously been used. The paper should there- be put to soak soon enough to have it ready by the time the negative is washed.

ing negative and paper into contact, and squeegee the paper the former. This should be done as quickly as possible

before the dye has time to "run" on the negative, and great care must be taken to avoid any slip of the paper when it is laid down on the negative. If any slip occurs a new piece of paper must be applied, and the negative must be again rinsed.

After a period varying from five to fifteen minutes the paper can be stripped from the negative and immediately pressed between blotting-papers. It is then put aside to dry thoroughly.

For some reason not understood the first pull from the negative often sticks to it and tears, but the bits of paper adhering can then easily be rubbed off. As the first print is almost always too flat this does not matter much, and subsequent prints have no tendency to stick.

When a print has been taken the negative is redyed for from two or three minutes, and rinsed before the next print is made.

The time of contact in printing varies with the negative and the dye, and the amount of dye the former will hold. In my own experiments I found ten minutes the average time, but a negative of exactly the right kind requires only about five minutes.

C. WELBORNE PIPER.

## THE MODERN NOTE IN THE DESIGN AND FITTING OF PHOTOGRAPHIC PREMISES.

### III.

Under this title we continue, with the following article, a series of chapters by Mr. Drinkwater Butt, F.R.P.S., on the principles which should guide the photographer in the external design and decoration of his place of business, and in the arrangement and appropriate equipment of its various apartments. Photography, being essentially an "artistic" business, taste and style need to be more in evidence than is necessary in businesses which are frankly and wholly commercial in their character. Therefore, while it is not possible to prescribe any plan which can be followed in particular cases, general rules can be laid down in such a way that a photographer can take advantage of them in giving his establishment, both inside and in, an air of distinction, which is bound to carry weight with his townspeople, and must turn out to his commercial advantage. Of course, a fortune may easily be squandered on such adornment of the studio, but in these articles Mr. Butt confine himself to such schemes as a photographer in a moderate way of business need not consider beyond his means. Moreover, the articles will be of assistance in pointing out how particular materials may be used, even on the smallest scale, in adapting or improving existing premises. The notes will conveniently be divided into four sections:—

Shop-front and Show-case.

The Reception-Room.

The Studio.

Planning complete Premises.

The last chapter will consist of a description of as complete a set of photographic premises as can be imagined—an establishment, in fact, which but few living photographers would feel justified in putting up. Yet the scheme in its various parts can be commended to the study of even the small photographer, on account of its detailing arrangements, which can be abstracted in pieces from their surroundings and utilised with advantage in businesses which are anything but magnificent in size.—Eps. "B. J."]

in importance to his shop window or show case, the reception-room of the photographer forms his principal means of testing and attracting his clients; and it is, therefore, here he should use his best efforts to make a really artistic display of his work. The late H. P. Robinson, who combined in a high degree the qualities of both the artist and the business man, once remarked that "the battle of the business is fought in the shop"; and of equal truth also is the proverb that "he who takes the eye takes all"; so that too much attention cannot be paid to this department. In considering the matter, it may be at once remarked that the two great faults to be found in many reception rooms are in their being often too much like a workshop on the one hand, or, on the other, of their being overcrowded with specimens, elaborate furniture, and bric-à-brac, until they rather resemble fancy fairs than suitable premises for the proper and dignified display of serious artistic

#### The Well Ordered Reception Room—Work Out of Sight.

In regard to the former fault, the obvious remedy is, of course, to let as little as possible of any of the work of produc-

tion be done in them; certainly nothing in the way of retouching, mounting, or framing, all of which cause a certain amount of dust, litter, and disorder, which are the last things which should find a place in any well appointed reception room. The utmost that may be allowed is possibly a little spotting, but even that is better done elsewhere, as it is certainly not desirable that clients should see work that is intended either for themselves or other customers in an unfinished condition, so easy is it for the technically uninformed to be prejudiced against it when in that condition. There is another proverb which says that "children and fools should not see anything until it is finished," and, although I hope that none of my readers may number many of the latter among their clientèle, I object strongly in the presentation to the gaze of actual or possible sitters of anything that is not absolutely finished and complete. This principle I have always extended to the showing of proofs, the practice of sending out unfinished ones leading, I believe, to many re-sittings which would otherwise have been avoided. Besides, if the photographer has not sufficient respect for his own work to desire to show it to the very best possible advantage, he can hardly expect his clients to have a great deal more.

Therefore, I say, keep finishing operations as much as possible out of the reception room, or, if any have, perforce, to be admitted, do them behind a screen or partition, which may, in itself, be made an artistic addition to the furnishing of the apartment.

#### Show a Little—But the Best—of Everything.

With regard to the second fault above mentioned, of the reception room looking like a bazaar or fancy fair, one must reiterate the advice given in the first article of this series respecting overcrowded shop windows and show cases, and plead for greater simplicity, which will bring, at least, some measure of dignity in its train. The specimens shown should, of course, include all the styles and processes produced, but only the very best examples of each should be shown, and each be placed in its most effective and appropriate position. Adherence to this principle will aid the artistic effect, give a high-class and dignified appearance to the whole, and enable the spectator to give undivided and undistracted attention to the work presented for his consideration, with the probable result of increasing his appreciation of it.

#### Furnishing the Reception Room.

The furniture of the reception room should be sufficient, but not excessive, in quantity, and in harmony with whatever style of decoration may be chosen for the whole. It need not consist of much more than a few comfortable seats and lounges for the use of clients, a roll-top desk or *escritoire* for the receptionist, and a few small tables for the display of specimens in books, small frames, etc. Whatever is used, however, should be good of its kind, and, if simple, yet artistic in design. Many admirable modern reproductions of the work of the best periods are to be obtained, at very moderate prices, from such firms as Warings, of Oxford Street; while very well designed and original furniture is a special feature of the business of Messrs. Liberty and Co., of Regent Street.

#### The Lighting of the Reception Room.

To proceed to the general requirements of a good reception room, we may note that one essential is that it should be well lighted, both by day and by night, during the latter preferably by electricity. As suggested in the previous article, the upper parts of many tall shop windows, which are useless for the external display of specimens, may often be utilised for the partial daylight illumination of the reception room beyond; and light may also generally be obtained from the back, when, as is generally the case with town premises, none is available from the sides. Best of all is, of course, top light, when it can be got, and this is a point which should be kept in mind when premises are being chosen for photographic purposes. Another good arrangement, and one which may be made to give very artistic effects, is, when there are three or more windows on one side of the apartment, to divide the space between them, by partitions at right angles to the wall, into bays, by which means a considerable amount of hanging space, lighted alternately from the left and right, is obtained. In these bays all kinds of work can be very conveniently displayed, while specimens of each kind of process are kept together, and yet isolated from possibly discordant neighbours. The quantity and quality of the lighting should also be taken into consideration when the general decorative effect is being decided upon, it being always to be remembered that a room not too well lighted should be decorated in a lighter key than one which has a better natural illumination; in which latter both the woodwork and the wall coverings may be darker in tint and tone.

#### A Caution to Amateur Decorators.

In the decoration of a reception room of an important character, it is generally best to keep to one style or period throughout, the Adams version of Renaissance work being, for instance, often very suitable, especially in one of the Georgian houses, of

which so many still remain in London and many other places, which style the ornament is sparing in quality, generally in relief, and the whole quiet and refined in taste, besides being admirably designed for execution in wood and plaster, the principal materials for indoor work. What, for want of a better name, is generally known as the "art nouveau" style is also not at all unfitted for reception room decoration, provided always (as the lawyers say) that its exuberances and extravagances be avoided, and its points of directness and simplicity seized upon. In the hands of such men as Mr. C. A. F. Voysey, Mr. George Walton, or Mr. M. H. Baillie Scott, who recognise the principle that fitness is always an element of beauty, and work simply, with many straight lines and a few flowing curves, and avoid over elaboration of ornament, this style reaches its goal of beauty through simplicity; and the would-be decorator cannot do better than study the works of these artists, or reproductions of them, which often appear, particularly, in the pages of "The Studio," a periodical which should be in the hands of all interested in the applied and decorative arts, and which is also specially deserving of support by photographers because it is, more than most artistic magazines, disposed to admit photography to its proper place among the latter.

#### Wall Coverings—Durable and Pleasing.

This, however, is a digression, and we return to the consideration of the permanent decorative features of the reception room. Among the most important of these are the wall coverings, they form the dominant note of colour, and also the background upon which the specimens of work will be mainly displayed. The most suitable materials for use are paper and canvas. The latter, in the better varieties, such as the "Tynecastle" and the "Holliston" makes, are naturally more expensive, but some of the cheaper forms of the material are also very suitable and serviceable. Paper may be also had printed with canvas effects, or the ingrain varieties may be used, both of which give a soft broken effect almost similar to that of canvas, which forms a very suitable background for photographic work. The "Tynecastle" canvases mentioned above, which are made by the Tynecastle Co., of Rathbone Place, begin at 2½d. per square foot, while the "Holliston" wall cloths, supplied by A. L. Gibson and Co., of Tower Street, Upper St. Martin's Lane, are about double that price. The latter are finer in texture than the former, and will be found to make an admirable lining for show cases, even where their price is prohibitive for the covering of large wall spaces. The cheaper kinds of canvases down to those used by paperhangers, and coarse linens and holland, may be obtained at all ordinary decorators' and stores. If a patterned canvas or paper is used, the design should be generally small, and of the "all-over" type, otherwise it will almost inevitably assert itself and destroy the quietness and restfulness which should characterise all backgrounds. In colour, delicate browns and greys are generally the most suitable, the brown of the wide continuous paper used for placing under carpets being often very suitable as a background for both monochrome and colour work. The writer recently used it in conjunction with a dach of coarse canvas for the studio of a well-known landscape painter with very considerable success. This material has the merit of cheapness as well as durability, and is easily renewed if in any way damaged. For newly plastered walls, on which it is not desirable to at once hang paper or canvas, the washable distemper known as "Duresco" is often a very useful and decorative covering, being made in very many soft, artistic and broken tints that are very suitable for our purpose. It is made by Messrs. J. B. Orr and Co., Charlton, S.E., and can be obtained from all painters and decorators. Very dull greens or grey blues may be also sometimes used for wall coverings, especially where there is a preponderance of pure black and white work, such as platinotype, to be hung, but for the generally used varieties of carbon and silver printing the greys and browns before alluded

It will be generally found the safer tints to use. For any small objects to be devoted entirely to the display of coloured work in frames, Indian or Pompeian reds are good background colours, though they are unsuited for the setting off of photographic work generally.

### What Not to Do with Woodwork.

Woodwork, speaking generally, may, if painted, be white, or brown, as may best harmonise with the wall covering, or, if natural woods are used, pitch pine, teak, mahogany, or oak are all suitable, but in any case none of them should be too highly polished. For oak a plain wax finish is what is required. The man of any taste at all will, of course, actively avoid the abominations of graining, marbling, *et cetera* omne! Small show-cases for miniatures and such like may be occasionally ebonised or black, but much black wood (apart, of course, from frames, which are very often best at colour) would produce a heavy and funereal effect.

### Formula for a Cheap, Good-looking Floor.

I have already spoken of floor coverings in the way of carpeting, in conjunction with these, polished wood block floors of pitch pine, teak, or oak, or thin parquetry of the same may be very effectively used in cases where expense is not so much

an object as artistic effect; or, where cost has to be considered, may be replaced by inlaid linoleum, or cork carpet, which, in parquet patterns, forms a very good and durable floor covering, especially where there is much traffic. Indeed, in a reception room which is directly entered from the street, I think that an entire covering of linoleum is preferable to carpet, as it is more easily kept clean and free from dirt, especially if when first laid, and at intervals afterwards, it is well treated to a good coat of beeswax and turpentine as ordinarily used for polishing stained floors. The latter (i.e., stain) is also a good substitute for parquet when there is already a good well-laid floor to operate on, but the common procedure of staining and then varnishing or using one of the so-called varnish stains is not to be recommended, as the surface so obtained will soon chip, scratch, and look shabby, and never give so satisfactory an appearance as a stain made of common Brunswick black diluted with turpentine to the desired brown tint, followed by applications of the above-mentioned beeswax and turps, or the wax polish which may be obtained in paste form ready for use. This gives a clean, non-chipping, unscratchable and, in time, well-polished floor better than any other method with which I am acquainted, and I have used it times out of number with entirely satisfactory results.

DRINKWATER BUTT, F.R.P.S.

(To be continued.)

## CONVERSATIONS ON COPYRIGHT.

### II.

**COPYRIGHT.**—The sole and exclusive right of copying, engraving, reproducing, and multiplying any photograph and the five thereof by any means and of any size. (Extract from the Copyright (Works of Art) Act, 1862). This definition puts in a nutshell the rights which accrue to the photographer under certain conditions. These latter were explained in the first conversation on "The Ownership of Copyright," which appeared

in our last two issues. The present series of questions considers the formalities which must be complied with in firmly securing the benefits of the Act to the owner of the copyright. It will be followed by others, in which assignment of copyright, infringement of copyright, and the intricacies of copyright in foreign countries will be dealt with. The articles aim at conveying the facts of copyright in simple form.

### THE REGISTRATION OF COPYRIGHT.

What is the registration of the copyright in a photograph? It consists in depositing at Stationers' Hall, London, a copy of the photograph, together with certain particulars.

Is it necessary to register a copyright in order to establish ownership thereon?

This is not necessary, but it is necessary to register before action can be instituted for unlawful reproduction or other infringement of a photograph. The Act says:—"No proprietor of any copyright shall be entitled to the benefit of the Act until registration, and no action shall be sustainable or any remedy recoverable in respect of anything done before registration."

Must registration be done immediately the photograph is taken?

No; it may be done at any time, but action can only be taken in respect to offences committed after registration. In other words, registration, in the eyes of the law, is a formal act, on the part of the photographer or other person, to the effect of securing the right.

What is the cost of registration?

The fee is one shilling, and the form in which entries are made costs one penny.

Must the form and photograph be deposited personally at Stationers' Hall?

They may be handed in or sent by post, preferably the latter, as any irregularity in the entries will be at once pointed out by the Stationers' Hall officials.

What particulars are to be given when registering?

A.: Usually only those asked for in columns 1, 4, and 5, viz.:—

1. Description of work.
4. Name and place of abode of proprietor of photograph.
5. Name and place of abode of author of work.

The entries in columns 2 and 3 are required only when transferring a copyright.

Q.: You might give me an instance of the way in which the form is filled up.

A.: Well, in column 1 should be a description—to the length of, say, a dozen words—of the photograph. For example, photograph from half-plate negative of Miss Isabel Jay as "Miss Hook," outdoor costume, full face. The photograph tallying to the description should be pasted to the back of the form.

Q.: In filling in column 4, name and "place of abode" of the proprietor of the copyright are asked for. Does the latter mean the private or business address of the owner?

A.: It has been held that the place of business is to all intents and purposes the "place of abode."

Q.: In giving the proprietor's name there are usually the alternatives of the actual name of the owner and the name under which he carries on his business. Which should be inserted?

A.: If the firm is a limited company its title (e.g., The Art Studio, Ltd.) should be inserted as the name of the proprietor, but if the business is a private one, the actual name of the proprietor should be given, followed by that under which the business is conducted; thus, F. L. Dovey, trading as The Vandyke Studios, 19, High Street, Margate.

Q.: As regards column 5—the author of the work—this, I take it, need not be the same as the proprietor entered in column 4?

A.: I think it has been made pretty clear that the name and address of the actual operator (not necessarily the proprietor) are required. The proprietor may be his own operator, but if a paid operator took the photograph his name and residential address must be given. If the proprietor of a studio has himself taken the photograph he will, of course, enter his own name and address in the space (column 5) pertaining to "author."

Q.: I should like to ask whether exact particulars are necessary as regards the author. When registering a copyright some time after a photograph has been taken it is sometimes difficult to be certain precisely who took the sitter.

A.: It is most essential that the particulars be correctly given. If, in a case in court, it can be shown that they have not been correctly given, the photographer may thereby lose an otherwise sustainable action.

Q.: I am sometimes told that my photographs are not protected from infringement (although I have registered them) because the word copyright, or the registered number, does not appear on them.

A.: That is not so. There is no need, under British copyright law, to mark registered photographs in either of these ways. In some countries it is necessary, but not here.

Q.: I have also been told it is a legal offence to mark as "copyright" photographs which have not been registered.

A.: It certainly is, though I know of no case in which action has been taken in respect to it.

Q.: How can I discover that a copyright has been registered at Stationers' Hall?

A.: Only by search in the indexes which are kept there. The fee for permission to do this is one shilling. The indexes are those of the names of the proprietors of the copyrights, not the authors thereof.

Q.: Is it not possible to obtain a statement from the Stationers' Hall authorities as to whether a copyright has been registered or not?

A.: No; the Copyright Office does not undertake to search. The only course for any one who cannot do it himself is to set a friend to look up the entries. The arrangement of the registers is such that it is easy to find if a given name appears. The hall is open for this purpose daily from ten to four, except Saturdays, when the hours are ten to two.

Q.: On registering a photograph, what certificate of the fact do I obtain?

A.: A receipt for the fee of one shilling is given, but this is not accepted in a court of law as legal evidence of the registration. For this, the certified copy of the registration is necessary. The authorities at Stationers' Hall supply it for 5s.

Q.: In registering a photograph I am sometimes in doubt as to the print to be deposited. Frequently, when the original print from a negative has not been satisfactory, I have worked

up the negative or an enlargement, or I have issued two-colour or three-colour reproductions of a print. My point is: Should I register the straight print from the negative or the final result? It may happen that I have several different varieties of the latter and I am not certain whether one registration covers all.

A.: In practically every case registration of one or other will protect both. For this reason, the Act defines infringement of a photograph more widely than copying it facsimile. A copy which is a "colourable imitation"—that is, unmistakably copy by hand, photography, or other process, of the copyright

Fig. 1.  
The original photograph.

Fig. 2.  
A palpably "colourable imitation."

photograph—is an infringement. A copy may vary considerably in general appearance, but if it present even only one or two features which prove it to have been copied from the original, it is an infringement just as though it were identical in every respect. Therefore, as a rule, registration of a straight bromide or P.O.P. print from the negative is sufficient.

Q.: If a number of photographs are copied together, say, on a smaller scale, and all registered together, will the one registration avail for each individual photograph?

A.: It will not. Only one subject may be entered on the form. Such a composite photograph would protect the particular arrangement, nothing more.

Q.: Suppose, however, that I photograph a group of portraits in a picture gallery, or a group of persons. Does the one registration protect me as regards reproduction of part of the photograph, say, one picture or a single face in the group?

A.: We can discuss such a question better under "infringement" in a later conversation, but I think there is no doubt that registration of an original photograph applies to every part of that photograph. It certainly does so in the case of the group, which must be regarded as an inseparable subject. The pictures might be considered differently, and I should say it would be wiser to register each copy separately, enlarging, if necessary, that portion of the negative.

**SULPHITE OF SODA.**—The writer of the note in the "Pharmaceutical Journal" which was recently published and commented upon takes exception in the current issue of our chemical contemporary to some extraordinary advice on testing sulphite given in an amateur photographic journal. The test is that of adding a solution of barium chloride to a solution of the suspected sulphite, and, applied as directed by the author, will show the purest sulphite conceivable to be the contaminated with sulphate. The "Pharmacist-Photographer" now writes:—"As a matter of fact, crystalline sodium sulphite, even in commercial quantities, is unlikely to contain any appreciable quantity of sulphate. The Pharmacopœia standard (97.28 per cent. pure sulphite) is, however, too high, and is seldom equalled even by recrystallised specimens. Messrs. Evans, Lescher, and Webb, in their recently published analytical notes for 1907,

report that commercial samples have been found to vary from 92 per cent. to 96 per cent., and this agrees with my own experience." The 'Agfa' handbook for 1908, after exhorting photographers to buy sulphite of the best makers, goes on to state that the salt of the manufacture has an average of 90 per cent. pure sulphite, a moderate claim in face of the foregoing facts.

"Since writing my former note on this subject, I have made further examination of the anhydrous sulphite there referred to, and find that the lower percentage of pure sulphite indicated is due to the presence of sulphate, and to remaining water of crystallisation. Probably this is unavoidable, as the sulphate may be formed in the process of drying, but as the authority quoted above remarks, 'a small quantity seems to be harmless in a developing solution.'"

# THE ENSIGN WORKS OF HOUGHTONS LIMITED.

EAR or two ago a former editor of this JOURNAL put the question, "photography played out?" and, in some thousands of words, answered it with an emphatic negative. An even more pertinent query is, "Is British photography played out?" and again the answer is an emphatic and unqualified negative, in proof whereof a host of facts and figures might be cited, but none perhaps more

ment, and we can imagine no more healthy corrective of despondency as to the solidity of the photographic industry than a visit to the spot which Messrs. Houghtons have peopled with a thousand busy hands, each aided by the best of modern machinery. A factory such as this is a new experience for Walthamstow, which has hitherto

One of the shops of the Ensign factory before the machinery was installed.

convincing in their evidence than the very concrete fact of the manufacture of photographic articles which Messrs. Houghtons Ltd. within the past two years have begun on the outer edge of the London East-End. Something more than fifty years ago the Houghtons were selling glass for collodion plates, since which time their business as merchants, wholesale and retail, of photographic articles has grown more and more rapidly, probably their anticipations of, say, twenty years ago—when amateur photography had become unmistakably a pastime for the

Metal turning and drilling shop.

been little more than a dormitory, where thousands of city hands come home to sleep, and it was no less an experience for us when we first had an opportunity of exploring its busy shops.

The Ensign factory is as fine an example as one could want to see of a commercial enterprise undertaken in a big, courageous way. In a business which calls machinery to its aid, the rule is "nothing venture nothing have." There is no comparison with the era of hand-manufacture when the money was spent on material and labour in proportion as the demand for an article increased. Your modern

Steel tools for stamping in the Ensign works.

man—did not picture a vast manufactory such as that at Walthamstow, employing all the resources of machinery in keeping pace with the orders of their city offices. If, indeed, such ideas of industrial expansion did float before the firm at that time they were very far put aside as the creatures of an exuberant fancy conjured into existence by a too sanguine view of the possibilities of photography. Yet the dream, if ever it took place, was but sober judgment.

Part of the wood-finishing shop.

factory cannot exist in this way. It must lay down expensive machinery for making a particular article, it must prepare tools, patterns and dies to the tune of hundreds of pounds before it is ready to put one article on the market. It must therefore do nothing until every detail of a new departure has been thought out, and the best form and construction of a new instrument decided upon. Thus it happens that the latest novelty in apparatus is very likely the final commercial form of a hand-made model which months before had been approved as embodying the manufacturer's designs, and thus the manufacturer, like the journalist, has to indulge in

"intelligent anticipation," and must constantly project himself months or years forwards if he would time the appearance of his apparatus with the fashion of the hour among photographers.

Such are the thoughts that slowly force themselves upon one as one makes a tour of a great works such as Messrs. Houghtons'. The first impression is that of incessant industry, of mechanical marvels in machinery, of the astute management which directs the passage of the separate parts of an instrument to a point of assemblage with the minimum labour and at the minimum cost. These palpable triumphs of the factory cannot be missed by the most non-technical person. But as one passes from foundry to machine shop, from the woodworkers to the fitters, and to the store-room of patterns and tools, one begins to appreciate the mind of this working body and to respect even more perhaps than the obvious perfection of organisation the commercial pluck which sets up a distinct commercial objective and spends money, brains and time in reaching it under the harassing commercial limitations. Get that idea into your head,

Building up dark slides.

and a tour through the big shops of the Ensign Works is trebled in interest. We see the different varieties of Sanderson cameras on their way from the unplanned board, which forms their bodies, to the assemblage of 150 working parts of wood and metal which constitute every one of these beautiful instruments. If we were better mechanics we could describe the feats of the lathes and cutters which fashion each one of these parts, but in doing so we might submerge the fact to which these operations are incidental—that is to say, the manufacturer's determination to produce, at the minimum price, an instrument which is as good for its purpose as can be made.

Seriously have the Houghtons' managers to consider how they can do their best for the user, for they have to spend a pretty penny, over and above the cost of stuff and labour, before the manufactured articles are ready for the dealer's customers. Yet, apart from this idea, which is gained only by moving from shop to shop, the details of the Ensign Works supply enough of interest to keep one loitering among its gangways for a week. The camera-user, and particularly he who desires to retain his instrument for many a long year, will view with satisfaction the large stacks of wood waiting under cover until thoroughly seasoned. The machine shop supplies a score of instances of the variety of Messrs. Houghtons' enterprises. Here a boy is collecting the metal ends of the roll-film spools as fast as they fall from a machine; there at a lathe, which dispenses with even unskilled labour once it has been set, screws of a rather complex pattern are turned out automatically; at other presses the tiny metal parts of the "Ticka" camera are produced by the gross and with the precision which this small apparatus requires. Equally in the wood-working shops the machines are as varied as the products which are required of them, and here, too, we see the result obtained with precision and almost lightning rapidity without the adjustment by that "clumsy tool," the human hand, as Mr. Shaw would say. When we have exhausted our superlatives in admiration of mechanical processes,

the bigness of the whole concern and of the output which it must represent make demands on our vocabulary. Messrs. Houghtons' something about 80 tons of brass used every year for camera parts that total millions. We believe it of the 600 machines in the factory. And it must be a satisfaction to the innumerable somebodies who purchase these cameras, enlargers, tripods, and other apparatus read of the supervision which in both earlier and later stages of manufacture maintains a high standard of workmanship. It will be understood what interest any one connected with photography cannot help finding in the Ensign Works. It is equally satisfactory to remember that the technical management of the works is in the hands of Messrs. Spratt Bros., Holmes Bros., and W. C. Jackson, all of many years' experience in the British photographic trade, and with Messrs. Houghtons, Ltd., to be congratulated on the prospect of their thoroughly British enterprise.

#### THIOMOLYBDATE TONING.

THE following new instructions have been issued by the makers of the "Cubrome" thiomolybdate toner, Messrs. H. Edmund and Mr. H. E. Smith, the inventor of the new method, has already communicated to our own and other journals the chief facts upon which the new toning process is based, and in a recent article the "B.J." Mr. C. Welborne Piper detailed some of the practical advantages of thiomolybdate over sulphide.

Care should be taken to tone for the full five minutes in the B solution, or the tone may be too dark a brown.

If, however, on drying the print is too dark, it may be modified again immersing in the bleacher for five minutes, washing out the bleacher (about five minutes in this case), and again immersing in the B solution (five drops or minims to the ounce) for five minutes after which wash twenty minutes as before.

A more simple method of producing warmer sepia tones if desired is to increase the amount of ammonia in the toning bath by adding from one to two drops of strong (.880) ammonia to each ounce of toning solution diluted ready for use. By this method a considerable range of rich brown tones may be obtained at will, suited for different subjects.

If after toning the whites do not clear readily from the light yellow stain, an immersion of from two to three minutes in dilute ammonia (3 per cent. strength) will be found to greatly hasten the elimination of any stain. Most varieties of bromide postcards and gaslight papers may well be treated with the ammonia clearing in this way, in order to shorten the final wash.

It will be seen that this toner possesses the following advantages over ordinary solutions for toning sepia by the sulphide process:

1. Bromide prints that are too flat in contrasts, and are not of good black tone to start with, which do not take good sepia tone by the ordinary sulphide process, will be found to take good tone with the thiomolybdate toner without difficulty.
2. The above remarks also apply to gaslight prints, while with this toner the tendency to yellowish tones with these papers will be found to be overcome.
3. It will be noticed that the odour of sulphuretted hydrogen which renders the ordinary sulphiding solutions objectionable is practically done away with in the Cubrome thiomolybdate toner in which few can detect the smell of anything but ammonia.
4. As this toning process slightly intensifies the print, the loss of crispness in a sulphided print (owing to the silver sulphide compound having less covering power than the original black silver) is overcome with the thiomolybdate toner; prints toned with it generally being noticeably more brilliant after toning, in spite of the image being turned from black to brown.

Finally, prints toned by this process may be considered fully permanent as prints toned sepia by the ordinary sulphide process since chemical facts that have been published show that the black silver image is by this process converted into the same sulphide compound of silver as in ordinary sulphide toning, while tests have shown that the addition to the image of a small portion of a sulphide of molybdenum by this process does not render the prints any more liable to change.

OWING to great demands on our space, the article on "Carbon Printing in the Tropics," by E. W. Foxlee, is unavoidably held over with several other articles and paragraphs.

# L.C.C. CLASSES IN WOMEN'S PHOTOGRAPHIC TRADES.

NEWLY ISSUED red-book of the London County Council gives the particulars of the classes inaugurated by the Council for women engaged in photographic trade work. The report is written by Miss Mannington, of the L.C.C. Trade School for Girls.

## CENSUS.

Between the years 1891 and 1901 the number of persons engaged in photography increased by 41.8 per cent. Amongst these the number of females increased by 56.4 per cent. In the latter year 51 females over the age of 10 years are recorded by the census employed in this industry.

## NUMBER VISITED.

During this inquiry 18 of the leading photographers in the profession were visited. Of this number one was an architectural photographer, one a photographer of pictures, four had factories (three in London, and one in the west-end and south-west districts of London, of whom seven were women employers.

## DESCRIPTION OF THE INDUSTRY.

By far the largest number of photographers specialise more or less in portraits; some include coloured platinotype and miniatures. The industry has made, and appears to be still making, rapid developments becoming highly specialised for various branches of science and art.

There are six firms in London who do only architectural photography, and the nature of the work somewhat precludes women from taking part in it. But in all the other styles of the work, it appears to be the general opinion that photography is essentially a women's trade, and well-trained women excel in all its skilled branches.

The various processes may be grouped as follows:—

- |   |                       |
|---|-----------------------|
| Operating.                              | 4. Printing.          |
| Developing, intensifying, and reducing. | 5. Fixing and toning. |
| Retouching.                             | 6. Spotting.          |

## 7. Cutting, mounting, and finishing.

Women of good appearance and manners are almost essential in selection-rooms, and they fill in their spare time with clerical work "spotting"—i.e., putting finishing touches to the prints with a brush. Sometimes printing is "put out" to be done.

Factory work consists of (1) developing, printing, and mounting of work of amateurs and some operators in the trade; (2) making slides and sensitised papers and packing the latter; (3) printing collotype, a process used for the reproduction of old manuscripts, microscopical slides, coins, etc.; (4) printing and packing picture cards; (5) colouring cheap photographs of views, etc.; (6) making negatives and sensitised papers.

## RELATION TO MEN'S WORK.

In factories women usually do the less skilled and the mechanical processes, while men do operating, printing, and the more difficult work.

In studios where a man is the proprietor he usually operates himself, while all the rest of the work may be given to either men or women, whichever he prefers to employ. Women generally do retouching, spotting, and mounting.

The number of women employers has largely increased during the last ten years; they usually prefer to employ women to do all the processes in their studios. There appears to be no obstacle in the way of women competing successfully with men in this industry.

## CONDITIONS AND METHODS OF TRAINING.

Portrait photographers frequently take apprentices or pupils, of whom inquiries were made, took two pupils who paid premiums varying from £10 to £50. They are usually taught all the processes, though some firms exclude operating and others exclude colouring. Sometimes girls are employed as "learners," receiving pocket money and paying no premium. They only learn one or two processes—i.e., those the most easily taught.

Objections are made by employers to spending time and materials in teaching girls the more skilled processes of developing, operating, printing, because of the uncertainty of their remaining long enough in the firm to be of use; on the other hand, the services of a well-trained woman are often retained during slack seasons on account of the difficulty of replacing her.

## WAGES, HOURS, AND SEASON.

Wages.—Wages, except for colouring and retouching, vary from 4s. to 45s. a week; printers' wages average 35s.; developers, 40s.;

spotters, 18s. to 20s. Cutters and mounters are the least well paid, their work being more mechanical, though not altogether so. Retouchers earn from £1 to £4, the average being about £2 10s. a week. Colour painting on prints in portrait studios is paid at the rate of 35s. to 80s. a week. Factory hands earn from 5s. to 16s., the average being probably about 10s. to 12s.

Hours.—The usual hours are from 9 a.m. to 6 p.m.; a few firms work from 9.30 to 6.

Season.—Photographic studios are generally slack in August, and more or less in September; the busiest time is six weeks before Christmas, and again in the spring. Sometimes there is a slackness again in January.

## PROSPECTS IN THE TRADE.

The prospects in this trade for a competent woman are good, for the following reasons:—

- (i.) All the processes are suited to her capabilities.
- (ii.) More women are entering the field as employers of women's labour.
- (iii.) The rate of payment is high in almost any branch in which she may wish to specialise.
- (iv.) No obstacles exist to prohibit her rising in her profession to a responsible position.
- (v.) It is a general opinion that there is a considerable demand for competent workers.

A girl likely to be successful should possess an artistic sense, good sight, delicacy of touch, precision, accuracy in detail and intelligence.

## DEARTH OF SKILLED WORKERS.

An almost unanimous opinion was expressed that there exists great difficulty in obtaining thoroughly skilful workers, and that the demand for them is increasing. On the other hand, there are too many of the inefficient and unintelligent class, and this is due to the absence of a satisfactory system of grounding and training girls.

## NEED FOR A TRADE SCHOOL.

This points to the need for a Trade School. Most firms are very unwilling to dismiss a good worker during slack seasons on account of the difficulty in procuring another later on in the season. Several employers consider there is a serious need of a practical system for training women in this industry. One large employer, on having the methods of Trade School training explained to him, said: "If you mean to train your girls in that way, when they leave, they will be snapped up at once." To quote another employer: "More women are employed in the trade every day, but they are in need of a more intelligent training."

The general opinion amongst the employers seen was that girls who possessed the necessary qualities and were well trained would have no difficulty whatever in obtaining work.

## SCHEME OF WORK.

The scheme of work suggested was that a thoroughly competent teacher should instruct the pupils in every process of photography for two years. Some chemistry might be added to this, not to train them for chemists, but that they should understand the properties and uses of the chemicals used in the various processes. Drawing should play a prominent part in their training, special attention being given to producing effects of light and shade, appreciation of line and proportion. It is important that a considerable proportion of the pupil's time should be spent in practical work in order to ensure precision and accuracy; but, on the other hand, it is necessary to develop the general intelligence of the pupil to obviate the danger of her work becoming purely mechanical. The success of the training would greatly depend on the advice given from time to time by a committee of experts, because the processes vary considerably in different firms and are often subject to change.

KENTMERE-IVORETTE £100 COMPETITION.—Messrs. Kentmere, Limited, announce a £100 competition for prints of technical excellence on their sensitised boards manufactured with P.O.P., gaslight, and bromide emulsion. The competition is open for a few weeks only, and the £100 will not be divided, but will be sent in to the technically best print. The Editor of "Focus" has consented to act as judge.

### THE SOCIETY OF COLOUR PHOTOGRAPHERS. SECOND ANNUAL EXHIBITION.

THE prospectus and entry form of the second annual exhibition of the Society of Colour Photographers has been issued by the Honorary Secretary of the Society, Mr. Henry J. Comley, and is obtainable from him at Surrey House, Stroud, Glos. The exhibition is to be held at the "little galleries" of THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, from June 1 to 27. The following are the conditions of exhibition:—

1. Exhibits are invited from all workers in all processes of colour reproduction, and are not to be confined to members of the Society.
2. All exhibits must be produced in colours, pictures coloured by hand will not be admitted.
3. Exhibits may consist of (a). Prints. (b). Transparencies. (c). Objects of Interest, such as series of constituent negatives, with transparencies or prints from same by any process.
4. All prints must be mounted, framing is not essential, but will be preferred. Passe-partout framing is advised, with rings affixed for hanging.
5. The attached entry form must be properly filled in—special attention being given to the required particulars of the method of production and must be forwarded to the Hon. Sec., Surrey House, Stroud, Glos., before May 12, 1908.
6. No entry fees are charged, and no awards are offered.
7. All prints or frames must have a label pasted at the back, upon which must be clearly written the name of the exhibitor, full particulars of the method by which the print is made, and the address to which the exhibit is to be returned.
8. Transparencies must have the name and address of the exhibitor written on the back edges, with the title or subject on the front.
9. The Society reserve the right to reject any exhibit which may be considered unsuitable.
10. All exhibits must be sent carriage paid, addressed to Henry J. Comley, Hon. Sec. Society of Colour Photographers, 24, Wellington Street, Strand, London, W.C. and must be delivered not later than May 15, 1908.
11. At the close of the Exhibition exhibits will be returned to the address given on same, carriage forward; but if it is desired that they shall be returned by post, a fully stamped and addressed wrapper must be enclosed with entry form.
12. While every reasonable care will be taken of exhibits, the committee cannot hold themselves responsible for any loss or damage arising from any cause whatever.
13. The signing of the entry form will be taken as an acceptance of all the foregoing rules.

A catalogue will be forwarded to each exhibitor.

## Exhibitions.

### WEST SURREY PHOTOGRAPHIC SOCIETY.

The twentieth annual exhibition of the West Surrey Photographic Society was held at the Railway Hotel, Battersea Rise, S.W., April 1 to 4 inclusive. Some excellent work was to be seen, including a small but creditable collection of Autochromes. The judge, Mr. C. J. S. Mummery, President of the Royal Photographic Society, made the following awards:—Silver-gilt plaque for best picture in exhibition: "A Woodland Path," G. Herbert. Bronze plaques: "A View in the New Forest," A. H. Butterworth; "Down River," F. J. White; "Suburban Snowdrifts," A. Lockett; "La Senorita," Mrs. W. H. Goy; "Hans," B. Gilbert. Honourable mention: V. T. Serin (twice), A. Lockett, G. Herbert, Mrs. W. H. Goy, and R. H. Baskett. Lantern slides: Bronze plaque—"By Stream and Hill," A. H. Butterworth; honourable mention—W. H. Goy and C. Pretty (Autochromes).

### BOROUGH POLYTECHNIC PHOTOGRAPHIC.

On Friday last the thirteenth annual exhibition of this society was formally opened by A. H. Blake, Esq., M.A., who also acted as judge. The show is an unusually good one, some of the works rising to a standard high enough to admit them with honours to any show in London or the provinces. All the pictures are the work of members, and the only classification is that of members who have

not taken a previous award and members who have. Of the latter the picture winning the highest distinction is "When Evening Mists Arise," a print of much beauty, depicting silver birches and gaining a silver medal. In the same class bronze plaques have been awarded to the following five works:—"A Normandy Peasant Girl," by J. Bedding, which is a view of a quaint corner in a courtyard, where a girl, a little self-consciously, handles a bucket as she stands well-head; "To the Light Beyond," by E. R. Bull, a view which seems scarcely well fitted with a title, unless the "light beyond" meant to be that of a stained glass window, seen between two columns in a church, where a bright gleam of sunshine strikes the foreground; "The Criticism," by A. G. Buckham, which represents a master and pupil standing before a painted canvas, a work of nicely composed lines; "Apple Blossom," by Miss M. A. Smart, a sprig, well chosen for form and tastefully lit; and, finally, a charming landscape called, "A Rainy Day," by A. J. Sturgess who errs if at all, upon the side of reticence in effect and elaboration in detail.

In the novices class the awards are two plaques and three certificates. Landscapes of much promise, by A. Challis and W. J. Cornock, and entitled respectively "River Mists" and "A Sussex Landscape," secure the plaques. The first is somewhat too dark key for the amount of definition shown, but it has excellent feeling; the other is creditably ambitious and good, except for a violent gradation in the sky. The certificates go to "Tacking," by T. Denny, a Thames piece, with a capital distance; "A Fair Prospect," by P. W. Gladman, a sunny, mountainous vista; and "Sunshine in the Woods," by W. F. Harrap, the secretary, whose official duties appear to have caused him to leave his bromide print too long in the bath.

The plaque in the lantern slide class fell to J. N. Spare, who showed also some excellent autochromes. There was a cheerful gathering to receive Mr. Blake's address.

### PHOTOGRAPHS BY THE LATE HORSLEY HINTON.

A memorial exhibition of photographs by the late A. Horsley Hinton was opened last Tuesday at the rooms of the Royal Photographic Society. Although only twenty-three pictures are shown, the impression is left upon the visitor that a mind peculiarly sensitive to the demands of landscape art had prompted the touches which lift these works above the level of ordinary photographic prints. It is scarcely one that is not excellently composed, and in one or two cases, where a general rule seems to be broken, there is evidence that a firm conviction and purpose had been responded to. Mr. Hinton had a way of making nature compose for him. In "May Flowers," for example, the blending of the foreground interest in composing lines with the middle-distance trees, argues a fine sense for these matters. "Reed Harvesting" on more ordinary lines is perfect in composition, and positively glazes with sunshine. Mr. Hinton's skies were sunny, and no one knew better than how to handle great masses of cumulus clouds to pictorial advantage. If he had a fault it was a tendency to flatness of effect. It is scarcely to be doubted that the highly romantic composition, called "Silent Glades," would have gained by strength among the pine stems. But he would probably have some good argument to advance in his choice. In "Recessional" there is more of this strength of colour and to our minds this work is, in this respect, one of the finest. "Over the Hills" shows the purest landscape feeling, dealing, as it does, with expansiveness, atmosphere, and light.

It is obvious in seeing these collected works, that the late editor was so successful in his journalistic career simply because he understood thoroughly what the amateur requires to be taught, and that that personal possession of the coveted knowledge which is above mere technicalities. A teacher and guide must be able to go further than the pupil can go himself with formulae and demonstrations to prime him. Those alone will not make pictures, though they may make photographs. Hinton could make pictures.

THE "RAJAR" CAMERA, offered monthly by Messrs. Rajar Limited of Moberley, Cheshire, for the best print on "Rajar" P.O.P., has been awarded to Mr. A. Holmes, 12, Kitchener Road, Selly Oak, Birmingham, this print having been judged the best during March. The paper on which the print was made was purchased from Messrs. Hurman, Limited, Victoria Square, Birmingham.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes."*

The following applications for patents have been received between March 23 and 28.

**EMATOGRAPHS.**—No. 6,874. Device for the mechanism of cinematograph cameras and projectors and the like, in which the film moves continually. William Thomas Coulson, 181, Maple Road, Henge, London.

**WATCH CAMERAS.**—No. 6,932. Improvements in watch cameras. Samuel Henry Crocker, 37, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**VISIBLE PHOTOGRAPHS.**—No. 21,223, 1907. The invention consists of a card or sheet upon which is mounted a bleached photograph. One piece with the sheet is a second sheet charged with the darkening or reproducing compound in such manner that it may be folded over or made to cover that part of the first whereon the picture is formed. To reproduce the photograph all that is necessary is that the charged portion of the sheet shall be damped and folded over so that it is brought into contact with the surface whereon is the bleached photograph; the photograph will then be immediately reproduced. Reginald Williams, 30, Finchley Road, London, N.W.

**ROTARY PRINTERS.**—No. 19,408, 1907. The invention relates to an arrangement in photographic printing apparatus with rotary printing cylinder and apron.

The principal feature of the arrangement consists in placing the angle of delivery—that is to say, in front of the delivery roller or between the latter and the feed roller—a rotary shaft provided with blades which, while rotating, lift the printing material away from the printing cylinder and compel it to proceed along the delivery path.

*a* is the printing cylinder, *b* the apron, *c* the photographic paper, *d* and *d'* the original tracing. The roller or shaft *f* provided with blades *e* is placed in the angle of delivery, i.e., in the space immediately to the right of the delivery roller *g* and a little farther off the left of the feed-roller *h*, marked in dotted line. My means chain or belting or pinion wheel gearing from one of the rollers *g* or *h* or directly from the motor of the apparatus the shaft is

used to revolve relatively swiftly. The means of driving are shown in the drawing. The direction of rotation of the different parts are shown by arrows.

When during the rotation of the cylinder *a* the edge of the printing material is just in front of the roller *g*, the pressure exerted by the apron against the printing material will cease; the printing material will then either rise spontaneously a little from the printing cylinder, or continue adhering to the latter. In the latter case the blades *e* will, however, when in their lowest position, or having passed slightly beyond this—see positions *e*<sup>1</sup> and *e*<sup>2</sup>—meet the edges of the printing material and lift them from the printing cylinder. According to the degree of disinclination of the edges to leave the cylinder, they will be subjected to

one single or several beats in quick succession, whereby they will necessarily be forced away from the printing cylinder and rise. The edges of the printing material will then, in the same manner as when spontaneously leaving the cylinder, be carried into the position shown, in which the blades *e* when nearing their horizontal position will, without any difficulty, push the printing material tangentially on to the delivery roller. The blades *e* may be made of any suitable material, as, for instance, india-rubber, and may individually be composed of a row of separate pieces. In order to obviate the drawback of the pressure of the apron ceasing suddenly along a line of the printing cylinder *a*, the guide-roller may at both ends be provided with a belt *b*<sup>1</sup> that is thicker than the apron, so that this latter just opposite the guide roller will be out of touch with the printing cylinder. Both belts may be carried in the same path as the apron itself, i.e., over the various rollers and around the printing cylinder. Hans Viggo Siim, Blegdams Hospital, Blegdamsvejen, Copenhagen, Denmark.

## New Crude Dames.

**HYPOXON.**—No. 300,560. A chemical substance for use as an eliminator for photographic prints, plates, and like goods. William Bailey Rogers, 6, New Square, Cambridge, liquid cleanser manufacturer, February 18, 1908.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Pictorial Photography and the Reflex Camera.

"My experience has convinced me" (writes Dr. H. D'Arcy Power in "Camera Craft") "that the universal camera of the future will be a reflex. While I think that its greatest triumph will be in extending the field of pictorial work, it can easily be constructed to serve all purposes. For all-round work the Premograph is an excellent little instrument. It is very light, it is simple to use, it makes a lantern plate by direct printing, and gives good enlargements. It takes time-exposures, and the shutter works fast enough for moving objects and detective work. Its chief fault is the limitation of the lens, which is a single fixed-focus achromatic. This means that good light is a necessity. Personally, I had no difficulty in overcoming this defect. I bought a Bausch and Lomb, 6in., Rectographic lens, mounted it in a focussing tube, and thus am able to work at *f*/8, and at any distance. To this I have added a lens-hood with a slot in front, in which I can drop a colour-screen or a plus or minus lens. With the first I can focus objects quite close to the camera, such as flowers or living insects; by adding a one-diopter minus lens I can utilise the draw of the tube and get a little larger distant view on the plate. This little arrangement has usurped the place of my old favourite, and is now always with me. It meets more requirements than any other camera I can obtain, and while thus fulfilling the needs of an advanced worker, it is the simplest thing the beginner can use.

## New Books.

Kelly's Directory of Chemists and Druggists. Eleventh edition. London: Kelly's Directories, Ltd. Price 20s.

This comprehensive directory of the chemical trades makes its appearance in its eleventh edition in a size and fulness which is a remarkable comment upon the largeness of the interests which it embraces. The directory deals not only with chemical manufacturers large and small, but with pharmacists, druggists, and other retailers of chemical products. But its chief interest to our present readers is its inclusion of photographers and photographic dealers. The Royal Photographic Society may perhaps demur to being placed at the head of the list of photographers, as the context gives them almost the appearance of a trading body. The other sub-divisions of the photographic trade are photographic apparatus manufacturers, card and mount manufacturers, photographic dry-plate makers, chemical manufacturers, photographic engravers, enlargers, makers of photo-

graphic films, lens manufacturers, photographic paper makers and importers, and photo-postal wrapper manufacturers, a classification which is certainly capable of improvement, since, to take one example only, it gives two lists which are, or should be, almost identical—namely, those of dry-plate makers and paper makers. If by photographic engravers, process engravers are intended, it is a somewhat curious fact that there should be but one entry—namely, Garrett and Atkinson, Warwick Works, Ealing, while under photographic films we have only the single entry of Houghtons Ltd. Under photographic lens-makers will be found one or two names of firms who can hardly be accused of possessing an optical factory. The provincial list, however, of photographers is a valuable portion of the directory, and from making a few references to it we should judge it to be an accurate and comprehensive compilation. The list of photographic materials dealers is a lengthy and evidently representative one. It is when we come to Kelly's compilation of photographic manufactures that we find cause for criticism. For example, to refer again to the heading "photographic films," we have just cited the solitary firm of Houghtons Ltd. in the London section, and we find in that for England, Scotland and Wales the one entry of Wellington and Ward, Elstree, Herts. The list of photographic enlargers too might be considerably augmented. In the list of photographic lens manufacturers we find no mention of Aldis Bros., Birmingham. We realise, perhaps as well as anybody, the difficulties in the way of making a proper classified directory of the photographic trade, but we think we might expect fewer omissions than those we have discerned at a first glance in the new Kelly list. As regards photographers and photographic dealers, errors may be readily pardoned in view of the large proportion of such firms who are constantly changing their address, but the firms constituting the photographic trade may be said to be pretty well established, and therefore their omission from lists which could have been compiled with more accuracy by consulting any of the directories published in photographic annuals or periodicals can hardly be allowed to pass without some comment.

"Lehrbuch der Projektion." By Dr. R. Neuhauss. 2nd edition. (Halle: W. Knapp. Mk. 4.)

Dr Neuhauss' treatise on lantern projection, it is scarcely necessary to say, is not primarily a handbook on how to make and exhibit lantern-slides. It is a description of the principles of and instruments for the optical projection of transparent and opaque objects, and viewed from this point of view the second edition shows the signs of able revision. Dr. Neuhauss has a way with him in writing on technical subjects, and does not mind letting fall a caustic comment on a method with which he cannot agree. Thus he hopes that the advantage of the rotating-lath projection-screen of Mr. Efic Bruce is better understood in England than it is in Germany, and he recommends the people who cry for a half-coloured screen (in order to have justice done to their slides of eventide) to try the effect of lowering the light in the lantern. The book briefly discusses the optical principles of projection, and describes the essential parts of the apparatus. In the section on slide carriers some elaborate mechanical devices are represented. Most valuable, however, is that portion of the book devoted to three-colour projection by the Ives, Wood, Lippmann, and Joly processes, the projection of opaque objects (aphengoscopes, etc.), panoramic and stereoscopic projection, and microscopic and cinematographic work. The volume is illustrated throughout by a number of drawings, and is, for readers of German, a most useful addition to the handbooks on lantern work.

Röntgen-Photographie. By A. Parzer Muhlbacher. Berlin: Gustav Schmidt. Mk. 2.50.

A new edition of this handbook on X-ray photography reaches us from the publishers, and is found to contain, in addition to a brief historical review on the discovery of the X-rays, a fairly complete practical guide on the making of radiographs. The second chapter deals with the general principles of X-ray work, the third concerns itself with the electrical apparatus required, and we thus have the author's recommendations as to the most advisable photographic procedure. Later chapters deal with stereoscopic X-ray photography and with the use of the simplest apparatus for galvanic electrical work. The volume is very fully illustrated with drawings of apparatus and with reproductions of radiographs by the author. For those who read German the volume should be a useful manual.

## New Apparatus, &c.

The "Premograph" Reflecting Camera. Made by Kodak, Ltd., 57 to 61, Clerkenwell Road, London, E.C.

That the Kodak Company have not been oblivious to the great and important advantages of the reflex type of camera has been abundantly shown by their active marketing of two instruments of this type, the "Graflex" and the "Premo," both of which were shown at the exhibition of reflex cameras held at "The British Journal of Photography" in June last year. The instrument which has now been submitted to us is not in any sense to be a competitor with the above more elaborate models of reflex, but serves to place in the hands of the amateur worker, and that at a most moderate price, part of the advantages which result from the use of a mirror. In other words, the "Premograph" is a quarter-plate camera in which a mirror is used to give a full-size image, and

although the camera is not provided with any focussing adjustment, the gain in certainty which the full size of image confers can hardly fail to be appreciated by the unskilled worker. The construction of the camera represents a reduction to the most elementary item further than which we can hardly imagine any camera of this type to go. The mirror is hinged at the upper part of the camera, and is set down by a winding key on the right hand of the body, or is allowed to spring up flush with the focussing screen by turning the same winding key in the reverse direction. Similarly, to the bottom of the camera there is hinged a corresponding

light metal plate provided with a velvet light-trap which forms with the mirror plate a shutter which can be used either for time or instantaneous exposures. For the former it is only necessary to set the small lever shown in the drawing at one end or the other of the metal plate, a turn of the winding key then commences the exposure and pressure upon the small knob concludes it. For instantaneous work the lever is placed centrally on the plate, and a turn of the winding key then gives an exposure which we should judge to be something like one-thirtieth of a second. The camera is provided with a hood of 5½ in. depth, which is self-erecting, and closes into a space of less than ¾ in. It is fitted with means for taking the Premo film-pack without adapter, and thus carries a supply of twelve quarter-plate exposures. At a price of two guineas the "Premograph" should find many adherents amongst amateur workers, who can fit it, if they choose, with a superior

as, or even with a lens in a focussing mount, which will greatly tend the usefulness of the instrument.

the "Rapide" Postcard Printing Frame. Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.

In this new printing frame provision is made for both P.O.P. and emulsion (or gaslight) work. This is done by adding a detachable handle to the hinged back by which the back can be quickly pressed into contact with the negative. For P.O.P. printing there are the

l springs. The frame itself is made double, with a recessed under-iron, accommodating a half-plate negative and mask. The frame consists of very rapid work, and should prove a most useful help to the postcard printer, amateur or professional. The price is three guineas.

## New Materials, &c.

C.C. Print-out Paper. Made by Ilford, Ltd., Ilford, London, E. The reasons why C.C. paper is so rapidly replacing the various forms of gelatine-chloride are not difficult to find. The emulsion of the new class of papers is not affected to any appreciable extent by variations in the temperature of the wash waters or solutions; no water is therefore necessary in hot weather; there is no chance of the prints sticking to the dish or to one another, and, if necessary, the prints may be dried by heat.

The superiority of the delicate matt surface over the glossy or varnished varieties of gelatine P.O.P., is generally acknowledged, whilst the glossy varieties of C.C. are available for work requiring full brilliancy. The chief advantage of collodion paper lies, however, in the wide range of beautiful tones, which are generally admired by the photographer. The black tones, for instance, obtained with ease and certainty by toning in gold followed by platinum, have a particular quality of their own, unexcelled by any other process.

The increase in the number of fresh makes of C.C. on the market amply indicates the growing use of this class of paper by the professional, and it may therefore be regarded as inevitable that the Ilford Co., in pursuance of its policy to supply the photographer with the best variety of sensitive surface, should include collodion paper in its list of printing materials, and it is evident that the firm's long experience in the manufacture of gelatine P.O.P. has been no obstacle to the production of a first-rate paper of the collodion class. We are of the new product as we have found it, after a fairly extensive trial, and we are bound to say that we have never used a C.C. paper that toned more easily in the baths to a good colour without the need of toning, or one so free from the usual defects of C.C. emulsion in the shape of blisters or minute surface cracks in a horny or uneven surface. And as we write we receive a report from a professional friend whose long experience of C.C. paper suggested to us the sending to him of a portion of our supply of the Ilford material. His verdict might be expressed in the words we have just used, and we are it is scarcely necessary for us to do more than to refer our professional readers to the Ilford Co., who are prepared, we understand, to send samples to bona-fide professional workers.

"Ilford" P.O.P. Postcards. Sold by James Spicer and Sons, 60, Abchurch Lane, London, E.C. 4.

Under this title a new series of sensitised material is placed on the

market by Messrs. Spicer, by whom only wholesale orders are executed. The cards consist of a fine sensitive material, matt or glossy, to which further variety is given by the tinting of the raw stock on which the sensitive preparation is supported. The four stock colours at present obtainable are sea green, sky blue, cerise and canary, all of which are sufficiently vivid to be quite unmistakable. Indeed, it may be questioned whether Messrs. Spicer, with the great resources in paper which they possess, have made the best possible selection among the uncoated materials to which they might apply their sensitive preparation. What we take to be the "cerise" is a nice enough colour, not unduly pronounced, but the other three, in our judgment, are of somewhat too aggressive a colour to permit of full justice to the really excellent qualities of the photographic image. Certainly the effects are striking, but there is the trouble, we think, that subjects for which such strongly coloured grounds are suitable are comparatively rare. However, it will be readily conceded that the products are distinct, and quite possibly occasions may be found to make effective use of them. The cards sell at from 10d. to 1s. per packet, and tone readily in the combined bath.

Challenge Semi-Matt Postcards. Made by the Challenge Works, Macclesfield, Cheshire.

A sample of these postcards, submitted to us by the makers, has given us most satisfactory results, both as regards the brilliance and clearness of the image and the surface of the paper. The makers certainly claim no more than is right in laying stress on the beauty of surface which they offer in the prints. The firm offer to send twelve gaslight postcards post free for 6d., and will send special quotations to large purchasers.

## CATALOGUES AND TRADE NOTICES.

"FALLOWFIELD'S COURIER."—With the April issue of the Fallowfield trade journal a list of reductions and alterations in price is included. There is also a description of the new Rapide postcard printing frame.

"THE RAINES SERVICE."—The pride in all that they do is shown in the new price list of Messrs. Raines and Co., of Ealing, of whose enlarging and printing services we cannot speak too highly. The issue of a beautiful piece of printing such as the list and the folder which more shortly describes Messrs. Raines' offers to professional photographers is proof enough of their refined sense of what is in good taste. A very necessary qualification this for an enlarging and printing firm, but, of course, not the only one by a long way. If such a firm had not also the means of originating and producing attractive photographic work, and that smartly and at a moderate price, they might as well go out of the business, and try and find a market for their fine taste in matters artistic. It is because Messrs. Raines have harnessed their genius in this respect to a very efficient commercial management that their output is unquestionably the hall mark of excellence in trade work for the photographer. We do their enlargements and folder portraits a poor compliment by dismissing them as "trade work," for we have constantly had occasion to be astonished at the extent to which Messrs. Raines have been able to carry out special individual requirements, and to apply their magnificent technical facilities to a customer's peculiar needs. Their new and comprehensive list should, however, be consulted for their standard productions in printing, enlarging, and finishing. It is sent free to bona-fide professionals.

SIR BENJAMIN STONE, M.P., will spend the Easter Vacation at Constantinople, where he proposes to investigate and photograph the ancient tombs from Sidon, which are now in the Sultan's Museum.

THE MARBLE ARCH.—The "Builder" points out that the original scheme for the improvement of the Marble Arch, proposed by Mr. Speaight, "has been distorted so as to lose all architectural symmetry and significance." In place of his semicircle, with the arch on the chord of the semi-circle, "what we now see on the County Council sketch is a lop-sided arrangement, in respect of which the arch has almost ceased to have any significance. . . . The improvement, as now shown, is well meant, and may be useful to facilitate traffic; but as an architectural scheme it is a blunder, and a good idea has been spoiled."

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, APRIL 10.

Loughborough Photographic Society. "Photographic Chemicals."  
Cardiff Photographic Society. Annual General Meeting.  
Nelson Photographic Society. Rotary Carbograph Paper.

SATURDAY, APRIL 11.

Hackney Photographic Society. "Lord's Bushes." The President.  
Chelsea and District Photographic Society. Excursion to Denham and Neighbour-  
hood.  
Liverpool Amateur Photographic Association. Excursion to Eastham.

MONDAY, APRIL 13.

THURSDAY, APRIL 16:

Handsworth Photographic Society. "Printing and Toning." J. Gough.  
Middletown Photographic Association. Hand Camera Night. By Members.  
Mill Camera Club. Portfolio Night.  
Liverpool Amateur Photographic Association. Excursion to Dovedale.  
Optical Society. "The Structure of the Eye." Microscopic Demonstration. Dr.  
W. Ettles, F.R.C.S., Ed.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, April 7, the president (Mr. J. C. S. Mummery) in the chair.

A short address was given by Mr. Reginald Craigie in introduction to the exhibition of photographs by the late Mr. Horsley Hinton now arranged in the society's rooms and briefly reviewed on another page. Mr. Craigie characterised Mr. Hinton's pictorial photography as embodying its author's keen sense of the grandeur of Nature. He believed that in time to come Hinton's photography would survive that of many of his contemporaries, and he uttered a warm appreciation of the deceased gentleman's personal qualities. Mr. Craigie also referred to the memorial fund, of which particulars are given in this issue, and appealed for contributions, even the smallest.

A demonstration of the gum-bichromate process was then given by Mr. C. Wille, who explained in some detail the methods which he had found best. He made his gum solution strong, 6 oz. in 10 oz. of water. The solution should be made in the cold, and a sample of gum selected which would completely dissolve in the above proportions in at most a couple of days. He found this strong solution to keep better than a weaker one. The bichromate he used in saturated solution, and for pigment preferred the cake colours which he mixed with water to form a thin cream which was afterwards mixed in measured proportions with the gum solution. In commencing work he found it well to start with one part of the pigment cream and add to it seven parts of gum solution, one part at a time, after each addition applying the mixture in a thin band to a piece of the paper to be used. He thus obtained seven strips of gum-pigment, each containing more gum than the preceding one. On allowing the paper to dry in the cold and placing it in cold water, he was able to ascertain the best proportion of gum which would allow of the pigment being completely removed from the paper in cold water. He made it a point to give the paper a slightly tinted substratum by applying a very thin wash of gum, pigment and bichromate, the pigment being usually either red or

yellow. This gave a toned effect to the print. As regards the proportion of bichromate, he adjusted it to requirements; the more bichromate the finer the grain of the print, and vice versa. The thickness of the coating was a very important part of the process, a thick coating giving a very hard soot-and-whitewash effect, whilst for a very flat negative a fairly thick coating was advisable. The pigments varied in the proportion of gum which they required, lamp-black requiring most. The demonstrator's method for exposure of gum prints was as follows:—He provided himself with two scale actinometers, each supplied with P.O.P., and he also exposed at the same time as one of these a piece of the same P.O.P. behind the negative. By exposing to light until a certain part of the negative was properly printed on the P.O.P., he ascertained the highest number of the actinometer made visible during this same exposure. He then placed a piece of gum paper in the same actinometer and exposed it side by side with actinometer No. 2 containing the other piece of P.O.P. Both were exposed until some number appeared on the P.O.P., when the gum print was developed and the highest number visible observed. If the number obtained on the first P.O.P. was 15 and that on the second 18, the simultaneous number obtained on the gum being 12, he subtracted 12 from 18, giving 6, and added this number to that obtained on the first P.O.P., namely 15. The sum of 15 + 6 (= 21) he then adopted as the number to be taken in exposing the gum paper by means of the P.O.P. actinometer. Over-printed copies he found it best to treat by soaking in water for times up to forty-eight hours. Further soaking than this was useless, and it was best not to use hot water for a shorter time as a hard print was the result.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held on Thursday, April 2, 1908, Mr. A. E. Smith in the chair. Dr. C. E. Kenneth Mees lectured upon "The Nature of Colour." White light, he said, was composed of various colours, which, when split up by the prism, were found to range from blue-violet to red, and the easiest way to remember its nature was to speak of it as wave lengths, the blue-violet being 4,000 and the red 7,000, the other colours coming in between these. The spectrum was thrown upon the sheet, and Dr. Mees showed how red absorbed all but red, in the same manner, he said, blue absorbed green, and so on. He put forward the theory that there was no such colour as pure yellow either in the spectrum or nature, but said that what was usually called the yellow band was in reality a mixture of red and green. This was illustrated by combining the red and green rays of the spectrum upon the sheet when yellow resulted. Given, he said, a drawing to copy, in magenta and blue green upon a white ground, to be reproduced in two printings, one would require to use a green and a red filter in the making of the negatives; for red and black on white, blue filter would be needed for the red, and a red filter for the black, this would reproduce the original as follows: The red-filtered plate first printed in red and the blue-filtered plate in blue, which, when printed upon the top of the red would give the black. He mentioned a filter which he had made which, when looked through, showed a landscape of nature as having a green sky with scarlet foliage. He then described the filters required for photo-micrography, shown on the screen the colour of the filters and the parts of the spectrum which they cut out. Following this, he gave shortly the basis of three-colour work, and showed that the three colours, blue-green, magenta and yellow, would reproduce all colours. It was, he said, necessary to adapt the filters to the colours that were to be taken. The lecture was very fully illustrated throughout. Dr. Lindsay Johnson passed round a chart of the spectrum which was interesting, inasmuch as it was a double one painted by a lady artist who was colour blind in one eye. In the one chart the colours and lines were shown whilst in the other no colours were given, although the lines were shown; the two paintings had been painted one with each eye. He also showed a pair of glasses which, when looked at by transmitted light, appeared a yellow brown, but which, when superimposed, changed to a bright red. Dr. Mees explained why the change took place. After a slight discussion the Chairman moved, and Dr. Johnson seconded, a vote of thanks to Dr. Mees for his lucid lecture and the Chairman presented to Dr. Mees the "Henderson Award" which he gained last year. Dr. Mees replied, saying that he was proud to be numbered amongst those who had gained this award and should always remember that the late Mr. A. L. Henderson had much for photography.

## Commercial & Legal Intelligence.

**PRO-GALLIC PAPER.**—In the King's Bench Division last week, before Mr. Justice Lawrence and a special jury, was heard an action by Mr. Charles Joseph Parr, a sensitised-paper maker, against Messrs. George Church and Co., paper factors and waxed paper makers, of Trinity Lane, E.C., for damages for wrongful dismissal. The plaintiff's case was that he had studied how to make sensitised paper, and after he had been in business with another firm, acting as the Premier Sensitised Paper Co., a suggestion was made that their business should be amalgamated with the defendants'. The plaintiff was to have £700 in shares in the company, and become manager at a salary of £200 a year. By his agreement he guaranteed to produce sensitised paper of a satisfactory merchantable kind. In the defence it was contended that the dismissal was justified, inasmuch as the plaintiff could not do what he said he could do. On Friday the jury awarded plaintiff £250 damages, and judgment entered accordingly, with costs.

**WINDING-UP.**—The Official Receiver in the Companies' Winding-Up Division of the High Court has now issued particulars under the liquidation of *Re Satino, Ltd.*, of 6, Church Row, Aldgate, E., from which it appears that the statement of affairs as regards creditors' gross liabilities amounting to £1,603 10s. 5d., of which £5 13s. 7d. is expected to rank against the estate for dividend. Assets are estimated to produce £457 16s. 10d., less £36 10s. for claims of preferential creditors payable in full, leaving the net assets at £421 6s. 10d., but as all the assets are covered by debentures, the net assets so far as the unsecured creditors are concerned are nil, and the deficiency £1,145 13s. 7d.

**ALLEGED THEFT BY A CANVASSEER.**—John Watt, described as a photographer's canvasser, of Butler Street, Bradford, was brought up last night at Keighley on a charge of stealing 2s. in money, the property of Mary Sugden, The Strand, Cottingley, from her house on Tuesday. It appears that between one and two o'clock in the afternoon, Mary Sugden, a widow, was in her house when Watt called upon her. He told her that he was canvassing for photographs, antique goods, etc. Sugden had placed a two-shilling piece on a shelf, and immediately he had gone she missed it. She went after him, and by a note got him to return to her house. Here she locked him in and went to the police-constable Curl, who returned immediately and placed Watt under arrest.

### NEW COMPANIES.

**Mawson and Swan, Limited**, has been registered with a capital of £30,000 in £1 shares, to acquire the business carried on at New-on-Tyne and elsewhere, as "Mawson and Swan," to adopt agreements with Sir Joseph W. Swan, J. B. Payne, and A. Payne, to carry on the business of manufacturers of and dealers in photographic dry plates, films, etc. There will be no initial public issue.

## News and Notes.

**CHANGE OF ADDRESS.**—Messrs. Tennant and Ward, publishers of "Photo-Miniature"; "The American Annual of Photography"; have removed from No. 287, Fourth Avenue to new and larger premises at No. 122, East Twenty-fifth Street, New York, to which all communications intended for their publication should in future be sent.

**LECTURES ON PHOTOGRAPHIC CHEMISTRY.**—Among the arrangements for lectures at the Royal Institution after Easter are three lectures on the chemistry of photography by Dr. Alexander Scott.

**THE "ENSIGN" ROLL FILM MONTHLY COMPETITION** for March has been held in the three-guinea camera being sent to Staff-Surgeon H. R.N., who is at present stopping at Sandown, Isle of Wight.

**PROPER PHOTOGRAPHS.**—The Criminal Court in Rome was filled last week with an eager and curious public, anxious to witness the trial of the German, Wilhelm Pluschow, aged twenty-years, and a native of Weimar, who is accused of various grave crimes against public morality. He is, moreover, charged with having sold and offered for sale on several occasions photographs of

a very improper character. Pluschow was arrested on May 11 last, as the result of a denunciation lodged by Signor Alfredo Marinelli. There was found in the studio a perfect host of dubious photos, on examination of which the police arrested Pluschow. As the result of their investigations, the police found that Pluschow very often went to a popular watering-place to obtain subjects for photography. It appears that his studio was frequented by a large number of people, including some high personages and numerous foreigners, the majority of them being Germans. Pluschow was found guilty, and an order given for his deportation from Italy.

**A "FRY" ENLARGEMENT.**—An enlargement now being shown in the window of the Rover Co., New Oxford Street, interests us for the evidence it affords of the excellent use which can be made of a small negative in the hands of a skilled enlarger. The subject, a line of motors outside the Ship Hotel at Brighton, was taken with a quarter-plate N. and G. camera by an amateur worker, Mr. Robert Head. The sepia bromide enlargement measures 60 x 30 inches, and is a tribute to the care and skill shown by the staff of Mr. S. H. Fry, of 5, Highbury Grove, London, N., of whose high average of work in the photographic processes it is a very fair specimen.

**TECHNICAL LIBRARIES.**—It is well known (writes the "Society of Arts Journal") that American employers give much more attention than has been the practice in this country to affording facilities to their managers and workpeople for obtaining technical knowledge. For example, a large organisation of spinners and manufacturers at Atlanta (Georgia) has adopted the following scheme for keeping their employees up to date in commercial and technical knowledge of the textile trade. A librarian is employed to secure all the latest books dealing with spinning, weaving, and textile engineering; all weekly, fortnightly, monthly, and quarterly periodicals bearing on the subjects are purchased, as well as every kind of year book. These publications are obtained from all parts of the world. The librarian prepares brief descriptions of the books, to which any one may refer to get a quick idea of the contents. In some instances the whole periodical is filed, in others special articles are cut out, and sometimes foreign articles are translated and pasted in scrap-books. Everything is carefully indexed, and the library is open to any employee.

**PRESENTATION TO MR. GEORGE DAVISON.**—That Mr. Davison, who is retiring from the managing directorship of Kodak, Ltd., has gained both the respect and esteem of his colleagues and fellow-workers was evidenced by an interesting little ceremony which took place quite recently at the firm's head-office in Clerkenwell Road, when Mr. F. C. Mattison, the secretary and assistant manager, on behalf of the staff, asked Mr. Davison's acceptance of a handsome gold watch. The gathering numbered representatives from the firm's London, provincial, and foreign houses, and Mr. Mattison, in speaking for all, voiced the general feeling of regret at the severance of Mr. Davison's long active connection with them, and also their satisfaction that, though in a less active manner, Mr. Davison would still give them the benefit of his assistance. In reply, Mr. Davison expressed his sincere appreciation of the kindly feeling and goodwill which had led to his fellow-workers putting their good wishes in so welcome a form, which would, he said, be a constant reminder to him of the friendly relationship which had existed between them during the long period—nearly twenty years in all—of his association with the firm.

**DEATH IN A STUDIO.**—The discovery of the dead body of a photographer named Alleyn was made last week at the closed studio belonging to the deceased, at Hastings. Alleyn's body was found with some indiarubber tubing fixed to the mouth, and death had evidently taken place some weeks ago. At the inquest it transpired that the name of the deceased was Henry Benjamin Allen.

**PHOTOGRAPHY, MUSIC, AND POETRY.**—At the Theatre Flamand (known also as the Théâtre Communal) in Brussels on Tuesday, the 31st ult., the members and friends of the Club d'Amateurs Photographes de Belgique held their tenth anniversary. Part 1 consisted of a very fine series of lantern slides of Venice, by M. Gustav Marissiaux. During their exhibition suitable vocal and instrumental music was performed behind the screen, and at intervals Madame Marguerite Radoux (the wife of the composer) declaimed connecting poetry. The effect of the whole was most charming and was greatly enjoyed. The third item in the programme was some Greek figure

studies, and the concluding series (also by M. Marissiaux) was called "La Bretagne." (Many of these Brittany pictures were very fine indeed; but the doleful poetry and music by which they were accompanied, although doubtless quite in keeping with the subject of the views, produced a rather depressing effect. The building in which the exhibition took place is a fully equipped theatre, with four tiers. It was crowded with a most enthusiastic and sympathetic audience, which took every opportunity of expressing its approbation at the excellent entertainment. M. Marissiaux has promised to show the above-mentioned series of "Venice" at one of the evening meetings of the Brussels Convention in July next. The members may therefore look forward with pleasant anticipation.

**MAULL AND FOX.**—The partnership between Herbert Fox and Frederick Glover, photographers, etc., carrying on business at 187A, Piccadilly, as Maull and Fox, has been dissolved, and all debts will be received or paid by Herbert Fox, who will carry on the business under the same style as before.

## Correspondence.

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### THE PORTRAIT POSTCARD.

To the Editors.

Gentlemen,—Referring to your letters in your last issue under the heading "The Portrait Postcard," I am much struck with the letter signed "Fair Trade and Fair Prices," possibly because it is just such a case as my own that he lays before your readers. I agree with him in everything, but having paid a £10 licence, I do not think I should be debarred from operating outside the district council area that I am situated in, as I have a valuable connection, and frequently have to go a distance of ten miles and perhaps into a town where there is another photographer. Not that my prices are below his, for they are higher, but I do better work.

He says: "Will the P.P.A. move?" Personally I have not yet become a member of that association, as I know of several professionals who do belong, and from what I gather from them they do not seem to think the interests of the country photographers are looked after sufficiently. If they would only put a stop (or endeavour to do so) to some of the travelling firms which are conducted by swindlers, and who employ men of their own stamp, I would gladly become a member, and do all in my power to assist in this direction. If the P.P.A. will not move, surely the country photographers can form an association to look after their own interests? If the profession would only hang together instead of trying to cut one another's throats, I am sure things would be better for all concerned.

I appeal to all country photographers to take some steps before it is too late.

I do sincerely trust you will keep your columns open for some weeks to come so that country photographers may air their views and see if something can be done to remedy those causes which often make the public look upon photography as a dishonourable profession.—Yours faithfully, **GOOD WORK AND FAIR PRICES.**

[Our correspondent speaks without knowledge when he accuses the Professional Photographers' Association of having done nothing towards combating the travelling tout-photographers. We refer him to the Association's annual report on p. 242 of our issue of March 27 last, from which he will see that directly and through the Press a good deal has been done.—Ens. "B.J."]

To the Editors.

Gentlemen,—I have read with interest the articles by "Fair Trade and Fair Prices," and others re "Portrait Postcards," and have come to the conclusion it is high time something was done to bring about a better state of things. It is absolutely ridiculous for any one to do postcards at 1s. 6d. a dozen or 1s. half a dozen. In my own little town I have found we must take them up or starve, but we charge 3s. per dozen, busts 3s. 6d., take only one negative, and submit no proofs, unless charged extra, and by using great economy

have been able to get a little out of it. The only advantage the postcards have, to my thinking, is in the fact I believe we get little in a good deal more often for postcards than we should do for cabinet or even C.D.V. portraits.

I scarcely agree with "Professional" in not turning them out if not good, for if we are going to make good pictures on postcards no wonder our ordinary work suffers. I simply tell our sitters that postcards are a special cheap line, and not near the quality of ordinary work, and give no guarantee whatever. I think, "Fair Trade and Prices," that if we are to see the photographic profession looked upon as an honourable one, and if we are to stand out the "postcard fiend" and "enlargement vampires," we must devise some means of petitioning Parliament to have photography duly licensed, and to be compelled to show same to police, same the motor driver, or be liable to a fine; and, to still further protect the country at large against these "wily serpents," to only give licences to persons on presenting a duly signed application, signed by, say, two Justices of Peace or clergymen. I think any respectable man or woman would be quite sure to find the requisite persons, if this could be established it should be effectual in ridding the country of all these "photographic frauds," and thereby giving once more "fair trade and fair prices." Finally, as a member of the P.P.A. since its formation, it seems a pity more photographers not join hands and unite together to try and elevate the profession once more to an honourable and respectable position.

ANOTHER COUNTRY PHOTOGRAPHER.

To the Editors.

Gentlemen,—I have also read with interest the various letters that have appeared in the "Journal" against the so-called innovation of the postcard. While deploring its existence I have, with many others, sufficient gumption to recognise that the demand has created the supply. As an outdoor photographer of some experience I have learnt, to my sorrow, that postcards "have come, and come to stay"; but, making a virtue of necessity, I work a little hard to reap the normal turnover, and I beg to smile in derision at the "arm-chair" photographers who, standing on their awful dignity, tell their customers "we cannot guarantee postcards." I note with amusement "Fair Trade and Fair Prices's" diatribe on the "postcard fiends," and the condign punishment he would mete out to all sundry who dared to try and live. I can almost hear him roar, "off the earth, ye postcard fiends and enlargement vampires; I do not fit that you should live, while 'I' am in my glass-house. Away ye itinerants!" But I throw not. We, the itinerants or nomads (call us what you will), are as open to as much consideration as more indolent superiors (?). We work for our living, and work pretty hard, and if four dozen exposed plates per day is any guarantee then business should be fairly brisk with our dealers as well as ourselves. That we "batten on the provender which properly belongs to another" I take exception to. One might as well think of putting a notice in the window, "Shop anywhere but here, if you dare." Let "Fair Trade and Fair Price" get out of his "arm-chair" go out and seek those customers which properly belong to him. In his impudence, to think they are going to wait his pleasure or commands.—Yours, etc., **ARCH FRENCH.**

To the Editors.

Gentlemen,—The portraiture postcard trade does not pay. Manufacturers are killing the goose that lays the golden eggs by producing them. It has opened a wide field for a certain section of amateurs and would-be professionals. Elated by their success, they have left other occupations and come forth into the world as full-fledged photographers. They have formed a profit from the ordinary commercial business basis, omitting weather and out-of-season vacancies. They have flooded the market with all sorts of work. So keen have they been to obtain orders that they have actually gone about photographing groups in different streets and sold them (P.O.P. enamelled) at one price each. Can anyone tell me how to do it? They have held photography up to ridicule by their crazy methods. Outdoor portraiture is completely crushed. Now they are making a raid on portraiture. Of course, they murder their subjects to a great extent. They have advertised the evil desire of the public demand for postcards. Wake up, ye sluggards, before it is too late.

sign a great big petition to the manufacturers and ask them to make some reasonable device to protect this wild goose chase of theirs. I should like to hear the opinion of the manufacturers on the subject.—Yours respectfully,  
FAIR PLAY.

To the Editors.

Gentlemen,—I have been much interested in the letters recently appearing in the "B.J." re the "Portrait Postcard," for I, too, have been in this particular direction. I read with particular interest the letter appearing in your issue of April 3 by "Fair Trade and Fair Play."

The idea put forward by him of requiring photographers to take a licence appears to me a step in the right direction, though I think his suggestion of £10 would hit hard in the case of a small dry business. The amount should be based upon average annual earnings. There is one point, however, which I would make a hard-and-fast rule—viz., that no one should be allowed to take out a licence on any account unless he were able to produce his indentures of apprenticeship.

Under the present circumstances, of what use is it for any one to apprentice their boys in the photographic line when any one, Dick, or Harry can buy a camera and pose as a professional photographer?

To point my argument, I may quote a case which has recently arisen in my district. Within half a mile of me there is a man until a short time ago was a bricklayer. Leaving that, he had a local glove factory as a glove-cutter, and opened a general at his house, and his latest departure is a camera, with which he takes photographs at odd times and supplies postcards to all and sundry at 1s. 6d. per dozen. Fancy the incongruity of it all! Such a man, I say, should not be able to pose as a photographer as the public is understood by the public, and if it was required that photographers be licensed, and, further, required to produce their indentures when applying for licence, then this class of man would be barred.

It is a far greater menace to the profession, and drags it to a lower stage, than the itinerant man mentioned by your correspondent, who is usually regarded by the public as largely composed of quacks and in a large percentage of instances is treated accordingly. I am, yours truly,  
INDENTURE.

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. Ten unmounted copies of each photograph must be sent with the application.

PHOTOGRAPHS REGISTERED:—

Money, 35, High Street, Chatham. Photograph of the Wesleyan Central Hall, High Street, Chatham.  
Hanson, 3, St. James Street, Guernsey. Two Photographs of Maj.-Gen. Campbell. Photograph of Maj.-Gen. Campbell and Capt. Campbell.

ING.—In the issue of your journal dated November 8, 1907 (p. 846-7), was described a patented focussing device, No. 22,238, of 1907. Possibly you may know whether this invention has been taken out on the market. If so, perhaps you will be good enough to let me by whom it is being worked.—H. V. R. SCHOFIELD.  
As far as we know it is not on the market. It would probably be expensive to make. Why not inquire of the patentee?

EDS.—The amounts paid are not very great, about a guinea for the sole copyright for postcard purposes, and some firms will

not pay as much as this. Your best plan is to select the leading firms from advertisements in the "Picture Postcard," published monthly, by E. W. Richardson, 42-44, Imperial Buildings, Ludgate Circus, E.C.

W. E. KETLEY.—We cannot explain the discrepancy, except by reminding you that the speed numbers are obtained by tests of plates, and different samples of the latter are liable to vary, also the tests may not be perfectly accurate.

STUDIO.—1. I am building a wooden studio in the country for high-class portraiture, and the architect and builder I am employing, though making no trouble about it, have not built a photographic studio before, so I should be glad if you can give me any useful information or tips, such as best width of glass, etc. 2. I saw in the "B.J." some time back a little joining piece recommended and illustrated which was to make join reliably water-tight, I think. Can you tell me who supplies them? 3. Is there any book published on studio building?—R. P. S.

1. On page 635, August 23, 1907, there is a practical article on studio building. On page 659 of the following week is an article on studio blinds, etc. If you consult those articles you will get all the information you require. 2. We cannot identify the paragraph. If you will write further we will try and find out. 3. Yes, "The Photographic Studio," a guide to its construction, etc., by Thos. Bolas. It is published by Marion and Co., price 2s.

FORM OF AGREEMENT.—I should be glad if you could inform me where I could get a form of agreement for an assistant to agree not to engage, or start in business, within a certain radius, in event of leaving present employment. Or if you could give some fair and reasonable terms for such agreement.—AGREEMENT.

Any solicitor will draw you out a form of agreement if you tell him the restrictions you wish to apply to the employee in the event of his leaving your employment. Possibly you have in mind the printed forms of wills, notices to quit, or the like, as sold by stationers. If so, we do not think they are to be had anywhere with reference to services. You might draw out an agreement yourself, but you had better employ a lawyer to do it, for there is an old proverb that "the man who acts as his own lawyer has a fool for a client."

BROMOIL.—In the bromoil process, though I have carefully adhered to the formulae and instructions, as printed in current number "B.J.," I find the image too fugitive in the bleaching process, and have lost a number of good prints, developed with amidol. Can you explain where I am probably at fault?—G. H. B.

We do not quite understand your difficulty, but assume that you mean the image will not reappear in the pigmenting. You may be using unsuitable paper or solutions that are not quite fresh. Try with some quite fresh ozobrome solution, and give a final soaking in water of about 70 deg. Fahr. Also be careful to fully develop the original bromides.

ANXIOUS.—The card is a poor bromide or gaslight print.

VANDYKE.—We have never been able to find any difference between the two; we believe they are both the pure substance.

S. H. C.—1. If the date of the publication shows that at least twenty-eight years must have elapsed since its appearance there cannot be any copyright subsisting in the engravings. 2. No. 3. It does not matter whether you offer for sale or do not, the copying of a work in which copyright subsists is illegal in either case. 4. This raises a legal point other than copyright, and we cannot answer it with any confidence. Our impression is that action could be taken at the subsequent date. 5. Separate markings on each engraving is not necessary when they appear in a book. 6. We should say that, legally, you cannot, but that actually the damage you will do to the authors of the copyright is so slight that they would not think it worth while to move in the matter.

INTENSIFIER.—I was given the following as a good formula for intensification:—

Anhydrous of soda .....	400 grs.
Dissolved in water.....	10 qzs.
Mercuric iodide .....	40 grs.

added after dissolution of the soda. After allowing this solution to stand for a few seconds it deposits a red precipitate, and, on well shaking, find it useless for intensification. Is it on account of want of knowledge in not first bleaching the negative, or is the composition wrong? Of course, I would naturally be guided by my com-

panion, the "B.J. Almanac," but my reason for asking you to help me in this matter is that I have to test the accuracy of my tutor before incurring further expense. Thanking you in anticipation. —DOUBTFUL.

It is not a very good formula, but it should impart some intensification to the negative. Why not follow the directions on page 799 of the "Almanac"?

**WILKINSON AND Co.**—General Waterhouse's papers were published in the Journal of the Royal Photographic Society (66, Russell Square, W.C.) about the year 1893.

**A DISREPUTABLE METHOD OF BUSINESS.**—A publishing firm in — sent on to me a box of pictorial postcards, accompanied by an account for 10s. As these were not ordered by me I replied to them, stating my disapproval of such business methods, and that if they forwarded sufficient money to cover postage I would return them. However, they advised me to retain them and endeavour to sell them, and sent on another account a month or so later. After tendering another some time further on I replied that the cards lay here at their own risk, and if they were not claimed within a certain period they would be destroyed. They replied that they would not take them back now, and to-day I have received a letter threatening to summons me if not paid by return. I would like, if you would say through your columns, whether they have any case against me in not refusing delivery of the cards in the first instance. The cards still lie here untouched.—A. M.

Decidedly not, as you offered to return them at the time if the people sent stamps to cover the postage. As to threatening a summons, that is all "bluff," and do not be bluffed. If you are summoned (which you will not be) simply state the facts in the Court and hand in the cards.

**SKAIFE'S PISTOLGRAPH.**—I have, in my collection of old photographic cameras, a little instrument, which was put on the market under the name of Pistolgraph, and was manufactured under the Skaife's patent, about 1881. Would you kindly tell me how the instrument was used, the kind of plate which were employed therein, etc.? I think that a notice about it appeared in the "B.J." or the "B.J. Almanac," and I would be very indebted to you for all information that you could give to me about the matter. The instrument produced little positive pictures, something like the ordinary ferrotype, but finer, and they were upon a dark coloured glass.—CHAS. MENDEL.

Skaife's patent is of much earlier date than that mentioned. It was 1856, No. 1,373. It is a small hand camera for taking collodion glass positives, as they required less exposure than negatives, and was furnished with a very quick lens and a very rapid shutter. If we mistake not, it was the first hand camera put on the market. It was very general at that period to take glass positives on dark or black glass, when the best results were desired.

**DAMAGED GLASS POSITIVE.**—I have frequently had glass photographs brought in to me to be copied, and have found that, by scraping the backing off and making a direct print, the final result is much improved. Last week I had one to copy and proceeded in the same way, but thought that I should improve by retouching the original. On my applying the medium most of the picture disappeared, and copying now is quite useless. I immediately removed medium with turpentine and re-backed with black varnish, but all that can now be seen is a very faint outline. I shall be glad to have your advice on the subject, as I am rather chary of tampering. Trusting you can help me out of my dilemma by favouring me with your advice in your next issue.—H. ADDINGTON.

From what you say, we expect the picture is quite ruined, and nothing can now be done with it. Possibly the picture had not been varnished, or, if it were, it was with a dammar varnish, which was the one usually employed for glass positives. Dammar is soluble in turpentine, and there is little doubt that the retouching medium dissolved it off.

**S. A. and Others.**—In our next.

**FERRO-PRUSSATE.**—As the gradation obtained by the action of light on the bichromates is remarkable for its evenness throughout the scale, while that of a ferro-prussiate image is decidedly poor in this respect, it would seem to me that, if one could convert the former image into the latter, it would be a distinct advantage

in cases where an evenly graded scale in ferro-prussiate is desired. Can you tell me how to do this?—THREE-COLOUR.

We cannot, nor do we think it can be successfully done. It requires the even scale yielded by the bichromates we also recommend you to make the prints in blue carbon tissue. It is an article of commerce, and is usually employed for three-colour work by the carbon process.

**MATTING PRINTS.**—I have been endeavouring to obtain matt surface portraits on gelatine paper by squeezeing the prints on to ground in the ordinary way with emery powder. The surface have obtained is not nearly so fine as some I have seen elsewhere. They also stick to the glass rather badly. I have seen somewhere the description of a way to obtain a very finely ground surface, the application to some acid fumes, but cannot now remember the way or where I have seen it. Can you help me in this matter, suggest a way to prepare the ground glass to prevent sticking?—CHAS. HUTCHINGS.

Glass can be matted by exposure to the fumes of hydrofluoric acid, but the latter is a highly corrosive gas, and we advise not to attempt using it. If you cannot get the effect you require with ground glass you will not get it with a finer glass. Should try preparing finest ground glass with beeswax, 20 g. turpentine, 1 oz.; rubbing this on with flannel, and polishing with silk rag.

**REPAIRING ACCESSORIES.**—Can you give me the ingredients used for the cement which covers the wood in the making of stoneware studio accessories? I have used plain Portland cement, but it comes off very easily, and makes a considerable mess on the floor when trodden on.—A.

We are not quite sure, but we believe it is common whiting, mixed into a paste with ordinary size, and laid on warm. For repairs you might try plaster of Paris, after the damaged places have been well wetted with water.

**ALBUMEN PROCESS.**—I shall be extremely grateful if you will give me a little advice. I have been in my present berth six months doing P.O.P., C.C., platinum, and a little carbon. My employer now wants albumen prints on paper sensitised at home. I am quite familiar with the working of the process through several years' work at my last place, though I have never actually worked myself. I can get on all right in sensitising the paper, printing, toning it, with very little waste. My difficulty is with the silver bath. After using it a few times it began to get tinted, eventually tinted the paper so much that it was impossible to get good whites in the prints. Then, unknown to my employer, I made up a fresh silver bath and all went well again, but now one is discolouring like the other. I believe there is some fault in preventing this, or at least of getting rid of the colour. Can you give me any advice?—FEMALE PRINTER.

All silver baths employed for sensitising albumenised paper become discoloured by use. They are decolorised by shaking them up with a little kaolin. The best way in practice is to keep a little kaolin always in the bottle—say, two or three spoonfuls in a Winchester quart bottle—and then return the solution to it after use, and well shake for a minute or two. By the next day the solution will be decolorised, and the bath, after filtration, will be ready for use.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received by the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

### SUMMARY.

E. J. Steichen, whose work in Autochrome colour photography has been much talked of for the past few months, has contributed to the "Camera Work" a full description of his methods, the essential ones of which we reprint on page 300.

A report of the L. and P. meeting announced for a demonstration of the "Thames" colour-screen plate appears on page 312.

The reception-room is further treated in the articles by Mr. Butt, who gives two photographs of the beautiful reception-galleries of Messrs. G. & J. P. & Co. reproduced. (P. 304.)

The sale and part-sale of copyright is the subject of this week's "Right Conversation." (P. 307.)

A further batch of correspondence on the portrait postcard will be found on page 314.

Welborne Piper has worked out a rapid and simplified method of determining the real working aperture of a lens by inspection. (P. 309.)

E. W. Foxlee refers, in a practical article, to the precautions to be adopted when working carbon process in the dark. (P. 303.)

The reduction of negatives by bleaching and cautious redevelopment is a recommended method, some practical notes on which are given on page 298.

The holders, a panoramic camera, and cinematograph mechanism are among the patents of the week. (P. 310.)

A paper on exposure in enlarging, Mr. J. Nixon combats some of the generally accepted views as to enlarging methods. (P. 308.)

Eastman Kodak Co., in its report for 1907, announces an increase of nearly £280,000 in its earnings. (P. 309.)

According to reports from Germany, progress would appear to be made in the production of a less dangerous cinematograph film. (P. 298.)

### EX CATHEDRA.

#### A Business End of Electro-photography.

One might look for light and airy persiflage in more likely places than in "The Ironmonger," which has a heavy, sober, Presbyterian sound about it, yet our contemporary cannot plead non-guilty to the charge of occasionally struggling to be gay—that is, if we are to judge from the "Trade Chat" in its current issue, where a writer ponderously frolics over a vexation of the ironmongering trade, of which we seem to have heard something in the photographic business, namely, the non-return of the photographs on which an ironmonger—foolish man—is in the habit of partially relying when he engages an assistant. It appears now that he is sometimes culpably negligent in returning these photographs, wherefore—and now we are coming to our contemporary's little joke—"The Ironmonger" suggested that the telegraphic transmission of photographs, or, better still, a process of telegraphic vision, will put an end to the trouble, and will permit of the negotiations being conducted in this fashion:

Hello! are you there? Is that Samuel Smoothspeech? I'm Obadiah Oldknow, of Oakton. You replied to my advertisement in "The Ironmonger" for an assistant. Your qualifications seem about right, but I want to see your phiz. Just switch on the telephone, please, and look as you usually do when serving a customer. Now let me see how you look when you're angry. Now give me your most seraphic smile. Thank you. That will do nicely. I will write you definitely to-night. Good-day.

#### Ortho-chromatism.

A little while ago the question of using ordinary non-orthochromatic plates with filter screen was again raised, and many strange statements and claims were made. It can easily be realised that a screen adapted to cut down the blue and violet light may be of service with photographic plates of all varieties, but when this simple fact is stretched so far as to make it appear that ordinary plates are as good as, or even more serviceable than, orthochromatic plates, the only result is the dissemination of a number of false notions with regard to orthochromatism in general. For example, we read in a contemporary that, "by suitable screening, any grade or range of orthochromatism may be realised with ordinary plates." Yet it requires no great effort of the reasoning powers to comprehend that if a plate is quite insensitive to, say, red, no amount of screening will cause the red to impress the plate. Some ordinary plates have a greater range of colour-sensitiveness than is generally imagined, but others are insensitive to certain colours, and with such plates the range of approximate orthochromatism possible is very strictly limited. It is interesting to experiment with filter screens and ordinary plates, but the fact that fairly useful results may be obtained with some brands of plates is no reason for either depreciating the use of orthochromatic plates with properly

adjusted screens, or for making all kinds of absurd claims for ordinary plates as a class.

### Reduction by Re-Development.

The method of reduction by re-development is one often advocated, but seldom practised, owing to the fact that faulty instructions have led more often to the spoiling of negatives than to their improvement. It is an old method, and the instructions given in most of the books that describe it usually prescribe the re-development of the bleached negative until the high-lights are not quite blackened through the glass. The plate is then fixed, and the final result too often is that the high-lights are found to be somewhat lighter than the half-tones, and so the negative is spoilt. These instructions describe a method that is capable of giving good results, but one that is very unsafe for the average worker. If they are modified slightly the process can be rendered not only certain, but far safer than any involving the use of solvents such as persulphate or cobaltamine. Any of the well-known bleaching solutions can be used, but perhaps the best is the familiar mixture of ferricyanide and bromide. Bichromate and hydrochloric acid is also very serviceable if plenty of acid is used so as to obviate the powerful intensification that such a mixture generally gives. When bleached and washed the negative should be re-developed with any convenient developer containing plenty of bromide. We generally use amidol with four grains of bromide per ounce of developer. The secret of success is slow development with a developer that acts right through the film, but does not readily give full density. If the development is conducted in a white porcelain dish, watched carefully, and stopped when the plate has apparently just regained its original density, it will be found on removing the plate from the dish and looking through it that it is very much thinner than it was originally, even though the image is blackened right through to the glass. If fixed at this stage the result may be too thin, and it is generally necessary to carry development a little farther. An experiment with a plate one half of which has been bleached will be instructive to anyone trying the process for the first time. If reduction is insufficient it can be repeated, or if carried too far it can be remedied by intensification. No detail is lost in the process, and all gradations are preserved if slow development right through the film is ensured. A hard negative can easily be converted into a beautifully soft one without the slightest risk of damage, and we look upon this method of reduction as one of the greatest possible value.

### Impure Sulphite.

A writer in the "Pharmaceutical Journal," from whom we quoted last week, states that: "Crystalline sodium sulphite, even in commercial quantities, is unlikely to contain any appreciable quantity of sodium sulphate." We frequently see it stated that if a sample of sulphite can be proved to contain a certain percentage of pure sulphite, then the rest of the sample is soda sulphate, and, as a poor quality sulphite is known to be capable of producing undesired effects in photography, all the blame is put upon the sulphate. We believe that up to the present soda sulphate has not been proved to be capable of producing any effect at all in development operations. It appears to be inert for all practical purposes, and, therefore, any ill effects must be charged to the account of some other impurity. We do not agree with the sweeping statement of the writer quoted above, but still it is a fact that in a sample containing, say, 97 per cent. of sulphite there can be no very appreciable quantity of sulphate, for the simple reason that there is little or no room for it. Such a sample must contain  $2\frac{1}{2}$  to 3 per cent. of carbonate, therefore the sulphate can only be present in

negligible quantity. We have never met with a 97 per cent. sample of sulphite, for 96 is the highest quality that has come into our hands. Recrystallised samples fresh from the best makers generally contain from 90 to 93 per cent., which strengths certainly leave room for an appreciable quantity of sulphate, and we have often met with good working samples containing only 84 to 86 per cent. These low value samples a considerable quantity of sulphate is undoubtedly present in addition to the carbonate, the quantity of which never exceeds 5 per cent., but also there are various decomposition products that have not reached the stage of sulphate, while bicarbonate is always to be found in a solution that has been mixed a little time. Some of the troubles caused by impure sulphite are, no doubt, due to the bicarbonate and to the decomposition products of the sulphite, but while we can attribute no definite ill effects to the sulphate, there is no need to ignore its presence. There can be no doubt that it always exists in the quality of sulphite commonly used by photographers, whether crystalline or anhydrous, though it is a very difficult matter to isolate it from other products of decomposition and determine its exact amount.

### FIREPROOF CINEMATOGRAPH FILMS.

UNTIL cinematograph films can be made of some less inflammable material than is used at present there will always exist the possibility of a recurrence of the terrible accidents associated with cinematograph entertainments, some of which have proved fatal. The use of celluloid films has been in many instances the direct cause of most of the fires which resulted in disaster. In order to remove this very serious objection numerous experiments are being made with the object of discovering a film that will be fireproof. Only a few years ago we were informed that preparation had been found that entirely met this demand. This was a combination of cellulose and viscose, composed largely of copper oxide and ammonia, and went by the name of azetylcellose. The quantity of spirit required in its manufacture was considerably reduced. But this material had the objection that it was neither sufficiently transparent, nor tough enough to withstand the wear and tear in the lantern rollers. Still, German chemists were convinced that azetylcellose would ultimately replace celluloid for cinematograph films, and as a proof of their confidence they carried out extensive experiments with it, and took out a number of patents for various modifications in its manufacture and preparation. The chief difficulties were to get transparency, flexibility, and toughness. When these were obtained it was usually at the expense of the main object in view, for these could only be obtained by the liberal addition of camphor and spirit, which meant that the new film had absolutely no advantage over the celluloid one.

Though these difficulties have not yet been entirely overcome, a very considerable advance has been made in the right direction. Dr. A. Eichengrün read a particularly interesting paper on the subject before the Society of German Chemists at the Danzig conference. He had been working on much the same lines as most of his fellow chemists, though he had been able to go a stage further, and had discovered a new azetylcellose preparation, which he calls "Cellit." This "Cellit" has been subjected to several practical tests, and from these would appear to be the most satisfactory substitute that has yet been discovered for celluloid when used for cinematograph films. First, all it is transparent, flexible, and at the same time so tough that it may be rolled or unrolled at a great speed for an almost unlimited number of times, without showing any sign of cracking, splitting, or other defect. On the contrary, it permits of the holes being made in it which are

ary for guiding it over the rollers, or spools, and ordinary care these will last an indefinite period with-  
aring. In short, the new film support may be used  
ctly the same way as celluloid is at present used, but  
this great advantage over celluloid, that it does not  
ily catch fire. Whereas celluloid when it is ignited  
off thick, choking smoke and a hot flame that it is  
impossible to put out, "Cellit," on the contrary,  
practically no smoke when lighted, and the small  
produced is easily blown out, as the fire has prac-

tically no hold on the material. At one of the practical  
tests a celluloid film was placed in position in the cinemato-  
graph lantern so that the direct rays of an arc lamp fell on  
it, and a "Cellit" film placed in the same position and  
under the same conditions. In less than three seconds the  
celluloid film caught fire, whereas absolutely no impression  
whatever was made on the "Cellit" film after ten minutes'  
subjection to the test. The discovery, if it realises all that  
is expected of it, should be welcomed by the cinematograph  
trade.

## THE MEASUREMENT OF THE EFFECTIVE DIAPHRAGM APERTURE.

ow to find the working effective aperture of a lens is a question often put to us by our readers, and is one in reply to  
a we usually recommend the pinhole method generally used for doublet and other non-single lenses. Mr. Welborne  
r now sends us a simplification of the methods which, so far as we know, has not been previously published. It has  
obvious practical advantages of requiring no apparatus other than a graduated scale, and of being performed in a few  
ds.—Eds. "B.J."]

majority of photographers measure the aperture by the  
l advised by the R.P.S., which is described in the  
Almanac for 1907, as follows:—  
e lens shall be focussed for parallel rays; an opaque  
shall be placed in the principal focal plane, the plate  
provided in its centre (in the axis of the lens) with a  
le; an illuminant shall be placed immediately behind  
n-hole, and the diameter of the beam of light emerging  
the front surface of the lens shall be the measure of the  
e aperture."

is an easy, though not the easiest, method of measur-  
ture, but, in spite of the quaint imperitiveness of the  
tions, it is not a strictly accurate one. It is not diffi-  
see that the method is only quite exact when the pin-  
infinitely small, and that if the hole is large enough  
through an appreciable amount of light, then the light  
from the front lens is not a simple parallel pencil,  
diverging bundle of parallel pencils of light.

most accurate method of measuring effective aperture  
means of a travelling vernier telescope, set parallel to  
ncipal axis of the lens, and travelling in a plane that  
through the axis. If this is focussed on the edge of the  
aperture seen through the front lens; a first reading  
n when the web of the eye-piece corresponds with one  
of the aperture, and a second one when the telescope  
versed across to the other side, and similarly adjusted,  
the diameter of the effective aperture of the lens is ob-  
with the greatest possible accuracy. No pin-hole at  
ncipal focus is required, yet, curiously enough, I have  
me across a description of a lens-testing apparatus with  
the telescope and pin-hole are used together.

telescope method is of course out of the question for  
erage worker, but, still, the method can be modified  
e same principle applied in an extremely simple manner.  
at is required is a scale (preferably of millimetres) of  
an inch square section, and so ruled that the division  
un nearly across the full width of the scale. The scale  
with its divided edge across the centre of the lens aper-

ture and pressed against the lens hood. The division lines  
being at right angles with the edge are also at right angles  
with the plane of the front of the lens hood, and therefore at  
right angles with the principal planes of the lens. By shift-  
ing the scale lengthways and sighting along the zero division  
we can easily arrange that line in alignment with one edge  
of the visible aperture. The other opposite edge will then  
be either exactly or very nearly in alignment with some other  
division line. If it exactly agrees, we can read the aperture  
diameter directly from the lines, while if it does not agree  
we can quite easily sight its position between two lines and  
estimate the fraction of a millimetre that agrees with it. In  
making the test it is best to stand so that light falls on the  
scale and makes the divisions easily visible. The lens need  
not be directed towards the light, as the edge of the aperture  
is quite clearly seen if we simply look through the lens at a  
sheet of white paper.

The scale can be made very easily by taking a square section  
piece of wood, three or four inches long, and pasting a strip  
of white paper on one side. When dry the scale is marked  
out, and the divisions ruled across with the aid of a set-square.  
The division lines must be at right angles to the edge, and  
the edge must be straight. The rule itself, however, need not  
be quite truly rectangular, so the most amateurish workman  
can readily make the appliance.

This is, of course, a far quicker method than the usual one  
with a pin-hole, and in principle it is a more correct method.  
The apparatus can be elaborated with a self-centring appli-  
ance that facilitates placing the edge across the centre of the  
aperture; and sliding sights and a vernier can be fitted for  
quite accurate reading. Still, with the simple form of ap-  
paratus described the photographer can measure the aperture  
of a lens with all the accuracy that he requires, and in a small  
fraction of the time required for the very common method  
that involves the use of a pin-hole and the exposure and de-  
velopment of a disc of paper fixed in the lens cap; which,  
by the way, is perhaps the most inaccurate way of applying  
the pin-hole method.

C. WELBORNE PIER.

AINS us to see the regrettable methods of hurried and irre-  
ple journalism penetrating even the arena of photographic  
ions. In the "Bath Herald" we read, in regard to the Bath  
raphic Society's exhibition, that "The judge will be Mr.  
Kimber, F.R.P.S., the well-known expert, and he has to-day  
he awards in anticipation."

BOLT COURT LECTURE.—On Thursday in last week Mr. Sherard  
Cowper-Coles read a paper entitled "Some Notes on Electrotyping"  
at the London County Council School of Photo-Engraving and  
Lithography. The chief features dealt with were the conditions  
necessary for the rapid electro-deposition of copper in the moulds  
and the effects obtained by mechanical and chemical treatment.

# COLOUR PHOTOGRAPHY WITH THE AUTO-CHROME PLATES.

(Part of a Paper in Mr. Alfred Stieglitz's "Camera Work.")

THE extreme thinness of the emulsion calls for general handling of the plate, but except during the memorable frilling period I have not used any precautions that one does not generally give to an ordinary plate. The one thing to avoid is to touch the surface of the film before development. The merest touch means a black fingermark, and probably it will come right across the face in a good portrait. Instead of the black paper supplied with the plates to protect them from abrasion in the holders, several French camera makers have made very useful special plate-holders that have an air-space behind the sensitive surface.

Any one that enjoys working in the dark with a nerve-racking alarm-clock certainly has the option to do so, but I like all the light I can get in the dark-room. The Autochrome emulsion is slower than some well-known orthochromatic plates, which I have developed with a red light, so why not the Autochromes? I first worked with a commercial violet and yellow celluloid safe-light, which gives a deep ruby light, safe for all reasonable use. Later I acquired one of Wratten and Wainwright's green lights, which gives not only more, but also a safer light. The loading and placing of the plate in the developer is done with my back to the light; at the end of thirty seconds the tray is brought close to the light for an instant to see how the plate looks. Then the necessary changing, if any, in the developer is done with my back to the light, and the plate examined every thirty seconds or so by transmitted light—quite close to the light. Giving an unexposed plate twice this amount of exposure during development did not show a trace of fog with the lights mentioned above. A safe light can be made by fixing out two unexposed gelatine dry-plates, thoroughly washing them, then drying. Dye one by immersing it in a strong solution of methyl violet, rinse and dry. Do the same with the other in a solution of tartrazine; subsequently bind the two together. If one is content with the Lumière time development formula the dark-room can be dispensed with entirely. A number of special daylight developing machines for this purpose have been put on the market in Europe. But I think the Premo Daylight Developing machine, which is made for ordinary plates, is really better than any other machine for the Autochromes.

The plate is put into a daylight developing-tray under cover of a changing-bag, the developer poured in, and at the end of two and a half minutes poured off and clean water poured in—or water with a few drops of sulphuric acid. The plate is then taken out of the tray and put in the permanganate bath, and so on.

When it comes to the question of exposure we are really up against the real difficulty. Many are the "systems" that have been worked out, and their efficiency is all of the same order—nil. The mechanical solution of the problem is still to be found. The best system I can recommend is the development of your sixth sense—exposure.

The makers of the plate give one a good guide to start with—one second at F. 8 in full sunlight on a summer noon. This exposure naturally increases with the time of day and year. On a clear, sunny day in the autumn I found two and three seconds the equivalent. The Wynne meter is also very useful as a guide—in the open air. Indoors it is useless. In the summer time the sensitometer number is about F. 11. For twilight exposure I found that the time required to tint the paper was the correct time of exposure. Indoors the question becomes still more complicated. With bright sunlight outside, a portrait near the window, with shadows lighted up by a reflector, is fully exposed in about one and a half minutes at F. 8. The best guide I find

is to give forty times the exposure one would give on, say, film in summer; in the autumn and winter, from sixty to eighty times as much.

The plate gets its maximum advantage of rapidity in brightest light, and its sensitiveness decreases altogether of scale and proportion to the ordinary plate in dull light. The use of stops this becomes very evident, for the ratio of exposure with the diminishing of the aperture is sometimes double the ratio we are accustomed to give with ordinary plates. But even greater importance than this is the influence that the quantity of light has on the colour-rendering.

It is strange how little people seem to realise that colour change, and change drastically, according to the intensity of light. No less an authority than Mr. Braun, the celebrated photographer of paintings, has been quoted as saying that light on the picture that is to be copied has no influence on result. If one has not the powers of observation, a reference to any scientific work on colour would prove the falsity of such statement.

Some colours are actually changed by varying the intensity of light; for instance, bright orange seen in a very weak light assumes a brownish tone, yellow takes on a decided olive green cast, and vermilion loses its orange tone, and looks a purplish red. In fact, the whole tendency is towards blue, which tendency is then further exaggerated on the Autochrome plate. A portrait photographed indoors on a dull, gray day has a cold, bluish predominating; outdoors the result is sometimes so blue that one imagines the plate to have been exposed without a sensitiser. A portrait done with sunlight falling directly on the subject is full of golden amber tones. The tendency of the plate is to exaggerate these effects; and often in landscape the light and blue effect is made more luminous by this exaggeration of the warm and cold tones.

I have tried compensating for this, but have only been so far to change the predominant tone of blue to either a green or yellowish one. But undoubtedly light filters could be used to compensate more accurately. A very excellent scientific explanation of this change of colour sensitiveness was given by Brasseur in No. XX. of "Camera Work," and I was surprised to find the photographic Press take it up. It is one of the most important points in the question of colour photography, and even in painting it has played a rôle, coming in for a good deal of experiment with Monet, and explaining in an admirable manner the blueness of his London series. I think the change of colour of things by moonlight is largely dependent on the same matter of intensity of light, for the violet and blue tones are preponderant then, to almost the exclusion of the other colours.

Although the lens does not play a very important part in the rendering of colour, I have found a difference in the work of a colour-corrected anastigmat like the Goerz Celor, and an ordinary achromatic lens. But it is a difference of hardly any importance to any but the scientific photographer. A lens slightly uncorrected for spherical aberration, but corrected for chromatic aberration, like the Smith lens, gives the most satisfactory results. It masses the colour and the planes of the picture better than an ordinary lens, besides giving that soft envelope of diffusion which makes the plates at times seem bathed with light.

## Developments.

To a timid, unadventurous individual, the formulae accompanying the Autochrome plates, with its numerous finger-staining solutions, must suggest an elaborate

licated process. But in reality, as a process, it is—or can be—simpler than any other photographic process in use, and for facility and speed in the getting of results, it stands on a par with that delightful old process, the tintype. Giving any consideration of the Lumière method for the moment, all demonstrate this claim for simplicity by describing my method of working. The first development is made with sodium in a solution of one part in from six to twelve of water. The development is carried to the required point the plate is removed under the tap and immersed in the acid permanganate for about two minutes for reversal—as soon as it is in this solution the rest of the operation can be conducted in daylight. The plate is then rinsed again and put back in the original developer until blackened; then washed under the tap for about a minute, dried, and varnished. The entire operation of development and even the washing and drying, can be accomplished in less than fifteen minutes. It is very important that the development be done in a bright light, and carried as far as possible. The question of fixing is still an open one. Theoretically, there is nothing “fixable” in the plate, but a number of experts claim that, in spite of this, fixing is necessary. Personally, I have found such joy in a process that can eliminate the hypo bugbear, that I gladly accept the nothing-to-fix theory, and generally do without fixing. In using the silver intensifier, I subsequently fix, for obvious reasons. Plates developed and without fixing, to the light of a window since June last, have not shown a trace of change.

One goes about the first development of the plate like any other, and one controls the image in the same manner, such differences as there are becoming evident with knowledge of the plate's peculiarities, gained by a few trials. Judging the development by reflected light—that is, looking at the film surface of the plate during development—the motion seems like that of a much over-exposed plate.

The transmitted light in the early stages of the development it enables the action of an ordinary plate. Then it gets a gray veiled look, that seems to brighten a little later, which is correct development normally. In cases of under-exposure development can be continued until an apparent reversal is reached—that is, the dark parts seem more transparent than the light parts. I have experimented in no end of ways to carry the first development right over into a direct reversal by overdevelopment or by fogging, but the results are not equal to those obtained by the permanganate reversal.

A plate which is slightly under-exposed and then developed in sodium, 1:6, up to the point of reversal will give a brilliant, high-contrast image, with stronger blacks than an image developed in a normal developer to the same point. A plate a trifle overdeveloped and developed about two minutes in 1:10 solution gives a beautiful soft positive full of modelling and colour, even in the shadows, and devoid of any very strong lights. This method is particularly applicable in developing plates of subjects with a great range of tone and landscapes in crude garish sunlight. Plates of this kind can be made richer in colour, still keeping the beautiful gradation, by intensification—in fact, a thin greyish negative plate can be built up to fiery effects of colour, to the point of exaggeration. With some emulsions I found that the development of under-exposure gave very garish colour contrasts, between warm and cold tones, which can be very useful in certain instances. A figure photographed in the open air towards sunset with half the normal exposure and forced development, 1:6 Rodinal, to the reversal point, gave brilliant orange tones and intense pure blue shadows; the whole as unlike the colour to a plate made at the same time, with normal exposure and development, as a Monet is to a Corot, whereas in the first and strength they were really alike. The same experiment with pyro developer gave still greater contrast. Autochromes intended for lantern slides should be both fully exposed and developed to get a gradation all over. This will give a

clear, thin positive that can stand a great deal of intensification, which is necessary for most projection slides.

Intensification is certainly the step of the Autochrome process least understood, and consequently most misused. Pictorially speaking, it need be used but very little, unless the picture is to be looked at through some dark peephole arrangement, when an unintensified plate will look grey and bleached.

For the way the average Autochrome is shown, if it is properly exposed and developed, intensification is unnecessary. If, however, intensity of colour is wanted, the resources are certainly there. The garish false colour one sees in so many plates is purely due to too much intensification; whatever defect there is in the colour rendering by the plates, whatever incongruous colour arrangement may have been perpetrated, trust the intensification to make it obvious. But the same holds true of a beautiful harmony of colour. The stronger the colours the more beautiful they seem and the more vital becomes the harmony. The simplest manner, of just slightly building up the image, is by immersing it in an Agfa intensifier, 1:15, for about a minute. This solution can also be applied locally with a soft camel's hair brush, to intensify a colour or build up a black, but its capacity is a limited one. Where a rich dark effect is desired the mercuric iodide is capable of very beautiful results. It also slightly changes the general tone, making it warmer and more golden—carried to its extreme limit in portraiture, one can produce the golden luminous glow that varnish gives to an old master.

Another great point for the mercuric iodide is that its darks are never opaque, as with the nitrate of silver or mercury. If the mercuric iodide image is still not intense enough, it can be further built up by a weak solution of bichloride of mercury, followed by a blackening in a developer. In extreme calls for blacks ammonia may be used to re-blacken, with astonishing results—but this makes the emulsion very brittle, and it shows a tendency to crack in a short time. Where a regular building up of the image is desired the Lumière nitrate of silver intensification is the best—and the only one to be recommended for lantern slides.

For reducing a weak solution of the acid permanganate bath is very satisfactory— $\frac{1}{2}$  ounce of acid permanganate in 16 ounces of water. But the hypo-ferricyanide reducer is better when the image is very flat, as it has the tendency to act more strongly on the high-lights. But any reducing other than what might be called a clearing up of the high-lights should be avoided, as the delicate colours are sure to suffer. However, under-exposed plates which would ordinarily be useless can sometimes be saved by clearing and then intensifying. The black spots which occur only too frequently in the plate can best be removed by touching them on the dry plate with a fine brush dipped in a strong hypo-ferricyanide solution. If they are reduced too far, it is easy to build them up again with a little colour. For the retouching of light spots a little lampblack water-colour will nearly always answer the purpose. I prefer to do this spotting before the negative is varnished, as the retouching is fixed in this manner.

It is astonishing how easy it is to do local reducing on the plate, and the professional photographer who is worried about moles and wrinkles can remove them as readily as he can on a black and white negative. This work is all done on a dry positive placed on a suitable retouching desk. The brush, dipped in the reducer, is shaken to remove excess liquid, and then the line or spot is brushed over or stippled. As soon as the reducer has acted sufficiently, blot it off with a good blotter, being careful not to slide or pull this; or the film will be torn at once. This process can be repeated till the desired effect has been obtained; naturally the plate is well washed after this.

The acid permanganate bath is best made up fresh every day or two, or it is apt to spread a disagreeable deposit on the film during the reversal. To facilitate this it is well to make up a very strong stock solution, by dissolving one-half ounce of per-

manganate of potash in sixteen ounces of hot water. For use take two ounces of this stock solution to a quart of water and add a quarter of an ounce of sulphuric acid.

The general colour of a plate can sometimes be helped by dyeing a cover glass to a pale tint of yellow. But this, as well as many of the after treatments I have referred to before, are dangerous tricks in the hands of the tyro. They are only intended for special purposes, or to save a plate that cannot be done again.

The varnishing of the plate is a factor of great importance, for the varnish acts as a protection to the thin, delicate emulsion, and makes the image brighter and more transparent. The gum dammar varnish has many disadvantages. It gets sticky with heat, and never seems to get absolutely dry. A celluloid varnish, Zaponlac, has the advantage of more completely isolating the film and of being insensitive to heat, but I have found this had a tendency to lift off the emulsion on some plates. The chief point in favour of the dammar varnish is the facility with which it can be removed, and its quick surface drying qualities. For lantern slides the celluloid varnish is best.

#### Concerning Artificial Lighting.

One of the most interesting sides of Autochrome photography, and one that does not seem to have been considered at all, is colour photography by artificial light. The use of flashlight makes instantaneous colour photography on Autochrome plates possible. The colour-screen supplied by Lumière gives a brilliant monochrome orange colour image by flashlight, very much the same colouring that some painters employ in lamplight effects. In this way it can be used very advantageously in combination with daylight. Popular and sentimentally realistic twilight effects could no doubt be produced by giving an exposure in full daylight, slightly less than normal, on a figure subject near a fireplace, for instance, and just at the end of exposure setting off a flash that has been arranged in the fireplace. The lens must be covered immediately, because the model is sure to jump and the room to be filled with smoke. I have tried nearly all makes of flashlight powder, and find the Agfa powder most satisfactory, giving least smoke and requiring least powder. The amount required is about ten times that used on an ordinary plate. Aside from the use of the flashlight for "realistic firelight glows," it can be used advantageously in many ways to produce warm reflections on an arrangement, in connection with daylight—this of course depending entirely on the judgment and taste of the photographer. I have made a great many experiments with a view to photographing in natural colours by flashlight and feel confident that much can be done in this way. Naturally, the regular screen is unsuitable for the purpose, as its absorption and compensation is calculated for white light—daylight—which flashlight does not equal. Of several dozen screens, that I have made and tried with all sorts of dyes, those made with Flavine, Chrysophenine, and one with Filter Yellow K, Hoechst, give

the best results. A slow plate is fixed, washed, dried, and then stained in a weak solution of one of the above dyes, by immersion for a few minutes, after which it is rinsed and dried. It is well to make a number of screens, of different intensities, and try them. A very pale screen is sufficient—it is best to make it on two glasses, as that will equalise any unevenness in the dyeing. The Filter Yellow K can be used lighter than the Chrysophenine, and it has the additional advantage of more completely cutting off the ultra-violet rays. I have made portraits in this manner that are remarkably true in colour rendering.

Naturally, these indications are but tentative, and thus of interest to the pictorialist only. The further development of the subject I must leave to abler and more scientific minds. The addition of one of the above mentioned screens to the regular Lumière screen, in daylight photography, gives some extremely interesting effects, with slight increase in exposure. The tendency is to make the colour warmer and richer.

I have often wondered why some one did not market suitably adjusted panchromatic collodion emulsion, with which one could coat spoiled plates, and thus use them again. It seems a pity to waste those beautiful screen plates, of which I have hundreds that have been used merely in endless experiments, which the wonderful fascination of this process has led me to make.

As regards the printing of Autochromes, the three-colour process affords no end of possibilities, such as gum, carbon, and pinatype. But other simple processes are under way, and the practical solutions of the problem are nearer at hand. I shall leave any more definite reference to the printing process for another article, when my own experiments have been more complete. But one thing we must not lose sight of; it is futile even to expect any process on paper, or other substance that presents the picture by reflected light, to give an exact reproduction of a colour transparency, any more than a painting on canvas can represent the effects of a painting on glass. In this way the screen plate will always possess value and beauty that are not to be copied—and colour that can not exist on paper. Furthermore and of particular interest pictorially is this fact: that what may appear very beautiful as a transparency, may when transferred to paper be absolutely horrible, for the richness and purity of the colour produced by transmitted light admits of colour arrangements that would be impossible, if attempted in the dull tones that reflected light would make of them.

There are colour harmonies which can only be indulged in when colours as luminous as in enamel or stained glass are available—such combinations are possible on Autochrome plates. This is one of the direct facts that point to colour harmony as the vital element to strive for in Autochromy. Personally, I have no medium that can give me colour of such wonderful luminosity as the Autochrome plate. One must go to stained glass for such colour resonance, as the palette and canvas are dull and lifeless medium in comparison.

EDUARD J. STEICHEN.

THE GERMAN PHOTOGRAPHERS' UNION will hold its thirty-seventh ambulatory meeting at Posen, from August 24 to 28 this year. There will be, as usual, connected with this meeting, a photographic exhibition, under the patronage of Her Majesty the Empress and Queen Auguste Victoria. The exhibition, to which every one will be admitted, will find, through the courtesy of the Governor of the province, Dr. Von Dziembowski, a suitable accommodation in the Kaiser Friedrich Museum (Professor Dr. Kaemmerer, Director). It will also be open to the general public till September 13. There seems to be every prospect that this new enterprise of the Union, which held its last year's meeting in Bremen, will prove a success. The programme, which will shortly be ready, will be forwarded gratis on application to the President of the German Photographers' Union, Karl Schwier, Weimar.

IMPROPER PHOTOGRAPHS.—At Tower Bridge Police Court last week Percy Thorm, manager at the establishment of Pastimes (Limited), London Road, Southwark, was summoned by Chief Inspector Drew of New Scotland Yard, for exhibiting a number of improper stereographic photographs in automatic cabinet machines. Mr. Charles Chapman said that it was a clear case, but he did not wish to send the manager to prison, because he did not think he was responsible. The maximum penalty of £25 and five guineas costs would be imposed.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On April 16 a demonstration of polarised light will be given by Mr. J. Briggshaw. This will be a special ladies' night, and visitors are sure to receive a hearty welcome at the meeting rooms, the Old Napier Tavern, 25, High Holborn, W.C.

## CARBON PRINTING IN THE TROPICS.

Those who work the carbon process at ease in this country have little conception of the difficulties that have sometimes to be faced by those who employ it in the tropics. Here all is plain sailing, as our temperature, except perhaps during an exceptionally hot day in the height of the summer, is not likely to bring about serious trouble. The case, however, is very different in many other places where the temperature reaches a very high degree, and at the same time is accompanied by great humidity in the atmosphere, as, for example, during the rainy seasons. At other times, when the air is abnormally moist, the tissue often becomes so brittle that it can scarcely be handled without the film cracking, unless it be specially made for such climates, and contains an extra amount of glycerine, or some such substance, to counteract the brittleness of the sensitive coating. A few hints on the subject of carbon printing in tropical climates may be of service to some of our readers who are workers of this ever-popular process in our countries.

### Instructions for Exporting Tissue.

Some troubles with the tissue itself will be first alluded to. The manufacture of carbon tissue is almost impracticable in tropical countries. As a rule, the tissue is imported from Europe, and mostly from England. On ordering, instructions should be given that tissue be packed in zinc-lined cases, which should be soldered down. Gelatine, as is well known, is an absorbent of moisture, and when at all damp is very prone to become mouldy. I have seen carbon tissue, as well as dry-plates, that have been returned from India entirely useless through mildew, although they were sent out in metal-lined cases. The actual cause of the deterioration was that the gelatine, when the plates were packed, was not thoroughly desiccated, hence, with the aid of the mildew germs that were in it germinated. It was the same with the carbon tissue. In exporting carbon tissue, the cases containing it should be specially labelled that they must be stored aboard in a cool place. When carbon tissue, by improper storage, has become mildewed, the mould can be wiped off and leave no apparent stain behind, yet when prints are made upon it the spots are sure to show. In short, it is useless to attempt to use tissue once it has become mildewed. When the tissue, properly packed, arrives at its tropical destination, its proper storage should at once receive attention. Should it happen during the rainy season the tissue may rapidly deteriorate, if not entirely worthless, through mildew. It should be transferred without delay to metal tubes or cases, and the latter made air-tight by sealing them with paper, or, better still, with an indiarubber surgical plaster, which is impervious to moisture.

Carbon tissue is always exported in the insensitive state, and sensitising of it at tropical temperature is one of the chief difficulties in working the process. It may happen that if a roll of tissue has been kept in an exceptionally hot and dry place it becomes so brittle that it cannot be flattened out without coating cracking. In such a case the best way is not to attempt to flatten it out, but to re-roll off about as much as is desired to sensitise, cut that off, and put it in a damp place where it becomes just sufficiently pliable to be conveniently handled.

### Precautions in Sensitizing.

It usually happens in places where high temperatures prevail that a plentiful supply of ice is procurable. In this case the sensitising-bath can be cooled down to a low temperature for use, either by surrounding the bottle containing it with ice some distance before it is required for use, or by putting ice in the solution. When this plan is adopted the bath should be made suffi-

ciently strong in the first instance to compensate for the dilution when the ice has melted. The temperature of the sensitising solution should be brought down, if possible, to 40 deg. or 45 deg. F., and the fingers put into it as little as possible. An important point to bear in mind is that the solution is absorbed by the gelatine much more rapidly when the temperature is high than when it is low, therefore a shorter immersion must be given to allow for the difference. After the tissue has been sensitised there comes the difficulty of drying it without the coating running off the paper, particularly when the air is nearly saturated with moisture. Gelatine is more soluble in a solution of bichromate of potash than it is in plain water at a similar temperature, a fact which obviously increases the difficulty in sensitising and drying the tissue in very hot weather.

### Spirit Sensitizers.

The difficulties involved in sensitising and drying carbon tissue may, however, be quite overcome by employing a solution that contains a very small proportion of water and a large one of spirit. Such a solution has but slight solvent action on the gelatine, and dries very rapidly. A good sensitiser for the purpose stands as under:—

Bichromate of Ammonia .....	6 grams.
Water .....	60 cc.
Methylated spirit .....	140 cc.

The bichromate is first dissolved in the water, and the spirit afterwards added a little at a time with constant stirring. This will give, roughly, a three per cent. solution of the bichromate of ammonia.

Or the following may be used:—

Bichromate of potash .....	6 grams.
Water .....	90 cc.

When dissolved add liquor ammonia until the solution becomes quite pale in colour; then add gradually 100 cc. of methylated spirit. This gives practically a three per cent. solution of the potassium salt. It should be mentioned that a very good form of spirit sensitiser is supplied by the Autotype Company.

The solution is applied with a "Blanchard Brush," which is simply a plate of glass with a piece of swan's down, or flannelette, doubled over one end and secured with an indiarubber band. A little solution is poured in a small dish, and the brush moistened with it, and then passed over the tissue, first lengthwise and then crosswise, so as to equalise the coating. The tissue may then be hung up, when it, in hot weather, will dry in ten minutes or so, and then will be ready for use. As the spirit has no solvent action on the gelatine, and there is so little water present, there is no risk whatever of the coating running. In this way quite large pieces may be sensitised without fear of brush markings showing, as the small quantity of the spirit sensitiser does not penetrate deeply into the coating, and it is only the mere superficial layer that is necessary to form the picture. I have sensitised pieces of eighteen and twenty inches, using an old half-plate negative to form the brush, with perfect success.

### Transferring.

It is imperative that the water used when transferring the exposed tissue to its support should be at a low temperature. Here ice may become necessary, and it must be kept in mind that gelatine absorbs warm water more quickly than it does cold; therefore only a short immersion should be allowed. Also, when the tissue is put upon the support, it should be well squeezed, so that as much water is removed as possible. When the exposed tissue has been got on its support the chief difficulty in working the carbon process at high temperatures has been overcome, and the remaining operations are quite plain-sailing.

When, however, the double transfer method is employed a later

trouble may possibly crop up in the following way:—Should the picture, on its temporary support, have become abnormally dry, there may be a tendency for it to split off before the transfer paper is applied. This, of course, may be avoided by not letting it get into that state, or, more certainly, by passing it through

water to which a very little glycerine has been added as soon as it has been rinsed after the alum bath. This will effectually prevent the picture reaching the splitting-off stage, and the glycerine will, for the most part, be washed out when the prints are being transferred to their final support.

E. W. FOX

## THE MODERN NOTE IN THE DESIGN AND FITTING OF PHOTOGRAPHIC PREMISES.

### IV.

[Under this title we continue, with the following article, a series of chapters by Mr. Drinkwater Butt, F.R.P.S., on the principles which should guide the photographer in the external design and decoration of his place of business, and in the arrangement and appropriate equipment of its various apartments. Photography, being essentially an "artistic business, taste and style need to be more in evidence than is necessary in businesses which are frankly and wholly commercial in their character. Therefore, while it is not possible to prescribe any plan which can be followed in particular cases, general rules can be laid down in such a way that a photographer can take advantage of them in giving his establishment, both outside and in, an air of distinction, which is bound to carry weight with his townspeople, and must turn out to his commercial advancement. Of course, a fortune may easily be squandered on such adornment of the studio, but in these articles Mr. Butt will confine himself to such schemes as a photographer in a moderate way of business need not consider beyond his means. Moreover, the articles will be of assistance in pointing out how particular materials may be used, even on the smallest scale, in adapting or improving existing premises. The notes will conveniently be divided into four sections:—

Shop-front and Show-case.

The Reception-Room.

The Studio.

Planning complete Premises.

The last chapter will consist of a description of as complete a set of photographic premises as can be imagined—a establishment, in fact, which but few living photographers would feel justified in putting up. Yet the scheme in its various parts can be commended to the study of even the small photographer, on account of its detailing arrangements, which can be abstracted in pieces from their surroundings and utilised with advantage in businesses which are anything but magnificent in size.—EDS. "B. J."]

#### A Suggested Reception Room.

To pass on to the remainder of our illustrations, we may next turn to the line drawing which I have made to embody some of

the principles, which I have endeavoured to also put into words. It is No. 12 of our cuts, and is a suggested arrangement of a reception room which forms part of the complete photograph

Fig. 12.—Arrangement of a Reception-room.

premises, the design of which will be dealt with in the last article of this series. In it I have intended to show how such an apartment might be furnished with a few antiques, such as any amateur might occasionally be able to pick up, as, for instance, the gate-leg table and the seventeenth century arm-chair shown to the left of the drawing, together with other furniture of modern make, such as that shown on the right hand side, some of which has been sketched in the show rooms of Messrs. Liberty and Co.

This room is really lighted from the side which is out of the picture, as well as from the window at the far end. It also

Fig. 13.—The Galleries at Messrs. Speaight, Limited, New Bond Street London, W.

ould receive some light through the opening on to the stair case wall; while it may also be noted that shaded reflectors are provided for throwing the electric illumination on to the work on the walls, in addition to the electrolier over the table in the centre and the shaded lamp on the receptionist's desk. These electric light fittings would be executed in beaten copper or polished bright iron, as best harmonised with the general colour scheme chosen for the whole.

It may also be noted that the walls are not overcrowded with specimens, a single line running round on the sight level, with a few larger ones above. The smaller examples are in frames

on the tables and cabinet, and others might be stored in the cabinet, or kept in specimen books or folios for ready reference.

The general design of the whole, and the few decorative features are of a simple and almost severe character, the relief to which would be principally in the smaller and more portable objects, such as the curtains, draperies, cushions, vases, etc. One would, of course, also introduce, as occasion and the season of the year allowed, some quantity of flowers, flowering plants, and shrubs, but never to the extent, as I have sometimes seen done, of making the place look rather like the show room of a florist than that of a photographer.

As regards general colour, one might suggest cream for the ceiling, with the cornice and frieze of the same slightly relieved with buff and dull yellow; the walls covered with a brown paper, with a dado of stronger brown canvas or matting, the woodwork of a dark warm brown, the floor of two shades of polished oak parquet, and the curtains and carpet in dull blue, ochre, and dull red, as also the furniture fabrics generally. The window would be of white glass to give the maximum amount of light, while the black beech chair to the left and the almost black oak of the gate-leg and small table to the right would give agreeable spots of dark contrasting tint. The appropriate inscription on the frieze might be done in dull red or gold, while the larger coloured specimens would be in gold frames, and the smaller and monochrome ones in brown, black, or white, as best suited the subject and process of each. It will thus be seen that the general effect would be sober and subdued, the few touches of brightness necessary for relief being obtained, as suggested, by the flowers and their vases, the lounge cushions, etc.

As our other illustrations, Figs. 13 and 14, we are very pleased to be able to give, by the special courtesy of Messrs. Speaight, two photographs of their reception galleries at New Bond Street. These galleries, which are certainly the finest in London, if not, indeed, in the world, will well repay study by photographers desirous of improving their own premises, for although all, of course, cannot go to the outlay which has here been made (the site and buildings here being worth at least £100,000), yet the principles of good taste and architectural fitness involved can be applied to work of even the smallest cost.

Study of our illustrations will show that although the decorative architectural features are, as befits a building of this size and importance, of a pronounced character, they are yet somewhat severe and simple in style, the late Renaissance period chosen being used with dignified restraint by the architect, Mr. C. H. B. Quennell, while the fine workmanship of the whole pleases the cultured taste and reflects the greatest credit upon the various firms who were engaged in the construction. The woodwork is of wax-polished oak, with only just sufficient carving in the caps of the pilasters, and on a screen under the roof (not seen in our illustrations), to relieve the general plainness; while the large restful surfaces of the walls and the almost plain vaulting of the ceiling should be especially noted as giving dignity to the general effect. In the whole place there is an absence of the restlessness, glitter, and garishness which characterise so much modern work, and which render it usually so very unfit for the surroundings and setting of works of art. The walls are covered with a paper reproduced from an old Florentine brocade design, admirably suited for the purpose; and the whole of the furniture, including the valuable Persian carpets on the polished oak floors is composed of genuine antique pieces collected by Messrs. Speaight over a considerable period of time. One of the latest additions, seen on a late visit, is a beautiful old harpsichord, which was being renovated and made fit to take its place as almost artistic and charming studio accessory. It should also be noted that the display of specimens is not large, a single row of framed enlargements running round the

walls, and a few smaller examples of work standing on the various antique cabinets placed beneath. The other specimens

present, I have only to add that the next article of this series will deal with the fitting and furnishing of the studio, and b

Fig. 14.—Messrs. Speaight's, Limited, Galleries: The Oak Staircase.

are kept in very neat and pleasing brown leather cases upon tables which do not appear in our illustrations.

Taking leave of these fine premises and of my readers for the

illustrated with reproductions of work designed by and executed for the author.

DRINKWATER BUTT, F.R.P.S.

## CONVERSATIONS ON COPYRIGHT.

**COPYRIGHT.**—The sole and exclusive right of copying, engraving, reproducing, and multiplying any photograph, and the negative of by any means and of any size.—Extract from the Copyright (Works of Art) Act, 1862.

In the two previous articles we have come to an understanding of how copyright is created and how ownership of it is secured, also the rights of such ownership; and, II., the formalities to be observed in registration, i.e., the formalities of proprietorship in copyright, without which the rights conferred by the Copyright Act are not legally obtained. We must now discuss the sale and part-sale of copyright,

and learn what precautions are necessary in granting rights of reproduction and in transferring a copyright from one person to another. The succeeding conversations will deal with the important questions of infringement of copyright, and with the privileges of owners of copyrights as regards foreign countries.

### III.—SALE AND PART SALE OF COPYRIGHT.

As I have gathered from our previous conversations, the right in a photograph is created by certain acts, and is established by certain formalities. I suppose, therefore, the Act suggests that copyright is something which can be bought and sold like other rights or privileges?

Certainly; the Act expressly refers to copyright as "personal or movable estate" assignable at law by licence or other legal document.

Written document? Cannot permission to reproduce be given verbally?

No; under the Act all licence to use or copy a copy-work "shall be made by some note or memorandum." Special clause of the Act (3) lays this down as an invariable

rule. But is a written permission needed on every occasion, for example, the case, say, of a photographer sending photographs to an illustrated paper?

It may not be necessary, if there is a standing agreement between the photographer and the publisher, but as the values of photographs for reproduction are very different, depending on a subject and the number of photographers who have taken it, it is advisable to draw up a licence in every case. A form of licence adopted by the Professional Photographers' Association is as follows:—

MESSRS. PEARSWORTH,

Of Carmietta Street, London, W.C.

In consideration of the sum of 10s. 6d., receipt hereby acknowledged, you are hereby authorised to reproduce by any process, in black and white, my copyright photograph of the *North Pier*, in the "Daily Herald," the reproduction not exceeding 6 x 5 inches, my name as the photographer to be printed under each impression, and a proof copy of the reproduction to be supplied immediately on publication. This licence is only for the purpose specified, for one issue only, and the reproductions may not be sold as independent pictures separate from the publication and its accompanying letterpress. The licence is not transferable, and no block or electro of the subject may be sold or disposed of without my written permission.

Dated this 27th day of March, 1908.

(Signed) F. WERNER,

Jacksonville.

I see here that the licence grants reproduction in one form only, implying, I suppose, that the photographer cannot grant as many separate permissions to reproduce as he

A.: Most decidedly he can. He can sell the sole copyright outright (with or without the negative, though usually the negative is included in such a purchase), or he can split up the copyright in various ways and dispose of the parts—that is to say, make limited assignments of the copyright—in every case in writing.

Q.: Perhaps you can give me an example of this subdivision?

A.: Well, in the case of an attractive portrait subject, a photographer might sell to other persons or firms:—

Right to reproduce in daily papers.

" " in weekly papers.

" " in books.

" " as photographic postcards.

" " as coloured (printed) postcards.

" " as posters or window bills,

which latter, again, might be further distributed among various distinct trades. In these cases, the person to whom permission was granted would have the right only for the specific purpose mentioned in the memorandum to him.

Q.: I see from this that it is necessary to define exactly the right which is being granted?

A.: Exactly; the licence should grant permission for a particular purpose, nothing more. For example, a form of permission such as:—

*Received of Mr. R. Meadows, the sum of 10s. 6d., for the right to reproduce my portrait of Lord Roberts.*

F. MORTON.

gives the purchaser (Meadows) the same rights as those of Morton, the proprietor.

Q.: Referring to the form of licence recommended above, is there any special object in naming the process and size of the reproduction?

A.: The reason is that it is usual to charge a higher fee for reproduction in the case of the more expensive processes, such as photogravure or three-colour. It is fair to assume that a photograph to be reproduced by one or other of such processes is worth more than one to be multiplied in half-tone only.

Q.: Also, the photographer's name is to be mentioned. I should like to ask if there is legal reason for this stipulation?

A.: No; none at all. The mention of the name is usually regarded by the photographer as his due, but he risks nothing by allowing it to be omitted. Many papers give preference to a photograph which they need not acknowledge to a photographer, but can ascribe, say, to their "own photographer."

**MARKS ON BROMIDE PAPERS.**—This is a subject of ever-growing interest to photographers, as the black streaks and markings appear, more particularly on glossy postcards, very much to the detriment of the prints and sometimes quite spoil them. Pressure and with any hard object or substance causes the coated paper to show these markings, as Professor Namias observes in the last issue of Eder's "Jahrbuch der Photographie." According to experience, carried out by the author, the keeping qualities of bromide paper depend to a very large extent upon the nature of the substrate, or under layer, the usual baryta and gelatine coating being of great importance. Glossy bromide paper, which is far more susceptible to

markings than matt, is coated on "baryta paper," and the emulsion is prevented by the heavy substratum from sinking into the pores of the paper, and the finished product seems for this reason to be more sensitive to friction. The usual remedy is, of course, to rub the dry prints with a piece of wadding moistened with Columbian spirit, but it is obviously easier to avoid the markings altogether if possible. Rubbing one piece of glossy paper against another in taking it out of the packet is sufficient to cause an "electric streak," and careful avoidance of friction is to be recommended throughout, in order to prevent what seems to be more or less of an accepted trouble with this class of paper.

## EXPOSURES IN ENLARGING.

(A paper read before the South Suburban Photographic Society by Mr. John Nixon, hon. secretary of the society.)

THERE is a curious consensus of opinion amongst the experts as to two points in connection with enlarging. They insist (i.) that it is impossible to determine the correct exposure in enlarging except by trial and error; and (ii.) that the exposure in enlarging by lantern does not follow the same law (if there is a law) as the exposure in enlarging by daylight. The first of these dogmas I have disproved practically by constructing an exposure meter, which gives the correct exposure with a daylight enlarger and diffused daylight, or with a properly constructed lantern, using a source of light large enough to give an evenly illuminated image of itself at the conjugate focus of the condenser, such image not being less in diameter than the working aperture  $a'$  of the lens. The second dogma I have similarly disproved experimentally in the case of incandescent gas illumination. Possibly it may hold good of certain kinds of lantern, especially where the source of light (a single filament Nernst, or a small arc light, for example), happens to be so small as to give a conjugate image at the lens, which fails to cover the working aperture. Where this happens even illumination of the disc can only be obtained by shifting the source of light so as to throw the actual conjugate image produced by the condenser behind the enlarging lens, the latter being thus taken to a point in the cone of rays near enough to the condenser to fill the working aperture with the blurred out-of-focus image. Naturally, the position of this point varies with the distance the image falls from the condenser, since the farther the image may be from the condenser the more attenu-

Fig. 1.

ated the cone of rays must be, and the farther along this cone must the lens be moved to find a sufficient body of illumination.

Theoretically, as well as practically, when the lantern is properly constructed and the light fulfils the condition above-mentioned, the exposure in enlarging with a lantern should always vary in accordance with the same general law as the exposure in enlarging by daylight. The latter may be deduced from Figure I.

Here A B represents the negative and E G the enlargement when the latter is of the same size as the negative, L being the enlarging lens; and  $a b$  the negative when the enlargement  $e g$  is to  $t$  diameters. If the amount of light passing through the lens were precisely the same for all sizes of enlargement, that amount of light would in each case be spread over the area of the enlargement, and the intensity of the light falling upon each area would naturally be inversely as the square of its diameter if all were circles, or the square of its side if all were rectangles. The exposure under these conditions for a  $t$  times enlargement would be the exposure for an equal size enlargement  $\times t^2$ . But the amount of light passing through the lens is not precisely the same for any two sizes of enlargement. It is evident that for an equal size enlargement (Fig. I.) the light passing through the lens is roughly that contained within the angle A L B, while the light passing for a  $t$ -times enlargement is that contained within the angle  $a l b$  or  $A_1 L B_1$ . The relative amount of light contained within these angles is roughly in proportion to  $A B^2$  and  $A_1 B_1^2$ , that is, to  $D^2$  and  $d^2$ , where  $d$  and  $D$  are respectively the distances between L and  $a b$  and L and

A B. But  $d$  is  $\frac{(t+1)f}{t}$  where  $f$  is the focal length of the enlarging lens and  $D$  is  $2f$ . Hence the intensity of the light passing through the enlarging lens for a  $t$ -times enlargement would be roughly

$\frac{4t^2}{(t+1)^2}$  times the intensity of the light so passing for an "enlargement" of equal size.

Correcting the result already obtained on the assumption that the light passing through the lens was constant for all sizes of enlargement, it is evident that, for a  $t$ -times enlargement, the true exposure (which varies inversely as the intensity of the light) should be, not  $t^2$ , but  $\frac{(t+1)^2}{4t^2}$ , or  $\frac{(t+1)^2}{4}$  times the exposure for an "enlargement" of equal size.

In enlarging with a lantern the problem of exposure presents different data, but, curiously enough, works out to the same result provided the lantern satisfies certain conditions, usually obtaining when the source of light is sufficiently large to give an evenly illuminated image at the conjugate focus of the condenser (where the enlarging lens is situated) of a diameter not less than that of the working aperture of the lens.

Where the source of light is an incandescent mantle or a three-filament Nernst lamp, with a ground glass globe to suppress the

Fig. 2.

separate images of the filaments, the exposure in enlarging follows the same rule as in the case of a daylight enlarger. With such an enlarger, if properly constructed, and if the enlarging lens is suited to the condenser, an image of the light should be thrown upon the enlarging lens by the condenser, when the apparatus is properly adjusted for any size of enlargement. This involves a variation in the position of the source of light, which in turn varies the intensity of the light passing through the enlarging lens. The problem is to calculate the extent of this variation.

Figure II. shows what happens when the adjustment is altered from that for an equal size "enlargement" to that for a  $t$ -times enlargement. For the former, C represents the condenser, L the enlarging lens, and I the light. For the latter, these are respectively C,  $l$ , and  $i$ . The distance between L and C is thus  $2f$ , where  $f$  is the focal length of the enlarging lens; and the distance between

$l$  and C is  $\frac{(t+1)f}{t}$ . It is evident that in moving the source

light from I to  $i$  the intensity of the light falling upon the condenser will vary inversely as the square of the distance between the condenser and the light. Calling the distance between C and I,  $D$ , and that between C and  $i$ ,  $d$ , this proportion may be expressed  $\frac{D^2}{d^2}$  and the intensity of the light passing through the enlarging

lens would vary in that proportion were it not for another factor which modifies the variation. This factor is the variation in the size of the image of the source of light at L and  $l$ , brought about by the adjustment. Assuming the light passing through the condenser to be the same in both cases, the intensity of the light

forming the image at  $L$ , as compared with that forming the image at  $L$ , will vary inversely as the square of the diameter of the image. Now the diameter of the image at  $L$  is practically the diameter

of the source of light  $\times \frac{2f}{D}$ , and the diameter of the image at

is practically the diameter of the source of light  $\times \frac{(t+1)f}{D}$ .

Hence the ratio of intensities due to variation in the size of the

image becomes  $\frac{4f^2 t^2 D^2}{(t+1)^2 f^2 D^2}$ , or  $\frac{4t^2 D^2}{(t+1)^2 D^2}$ . Combining the two factors

thus obtained, viz.,  $\frac{D^2}{d^2}$  and  $\frac{4t^2 D^2}{(t+1)^2 D^2}$ , we find that the intensity of

the light passing through the enlarging lens when the enlarger is adjusted for a  $t$ -times enlargement, is equal to the intensity of the light so passing for an equal size "enlargement," multiplied by

the factor  $\frac{D^2}{d^2} \times \frac{4t^2 D^2}{(t+1)^2 D^2}$  or  $\frac{4t^2}{(t+1)^2}$ . If the light passing through the

enlarging lens were always of the same intensity the exposure for  $t$ -times enlargement would (as with a daylight enlarger in similar circumstances) be  $t^2$  times the exposure for an equal size "enlargement." Since, however, this light, instead of being constant, varies

intensity in the ratio  $\frac{4t^2}{(t+1)^2}$  the exposure must vary inversely in

the ratio, and the factor for exposure, from being  $t^2$ , becomes  $\frac{t^2 t + 1}{4t^2}$

$\frac{t+1}{4}$ , that is to say, the same factor as we obtained in the case

a daylight enlarger. The accuracy of this result for all practical purposes I have tested with a gradometer, and have found it sufficiently correct. Based upon the conclusion I have constructed a meter which, combined with any reliable densitometer, gives a true enlargement from any suitable negative. But the factor and meter both fail to give accurate results directly the image of source of light thrown upon the enlarging lens by the condenser becomes smaller in diameter than the working aperture of the lens.

The exposure meter for enlarging, above referred to, is constructed upon the sliding scale principle, and is based upon a scale of light intensities working, for daylight enlarging, with a test paper of same speed as the Wynne meter. The exposures indicated vary with the speed of the plate or paper, the aperture of the lens, the number of times of enlargement (linear), and the density of the negative. The latter may be measured with a Dawson's densitometer, or, more accurately still, with an ordinary gradometer having numbered tints. Use with a lantern the Wynne meter, or the test paper used, may be dispensed with, and the actinic value of the light ascertained by using backward with the enlarging meter. A negative of known density (according to the densities used) is placed in the carrier, by the usual method of trial and error, the correct exposure obtained for an enlargement of equal size. The density number of negative on the meter is then set to that exposure figure, the aperture (on the meter) to the "Times of Enlargement," "1," the paper speed (known) will then appear opposite the correct value. So long as the same light is used, with ordinary care, to obtain the same efficiency, the figure so obtained may be used as, for practical purposes, the actinic value of the light for enlarging. And it is desired to work with any particular gradometer, say a Wynne-made one, the operator simply uses it in the carrier as a test paper, and gives, say, 12 (or 18) different exposures on so many of, say, Wellington bromide, for equal sized "enlargement," the exposure corresponding with the successive figures in the exposure column of the enlarging meter, as indicated for the twelve densities of Dawson's densitometer (with, say, three extra at each end of the series to make eighteen). He develops these equally, and marks in the column of densitometer numbers, opposite each figure given, the number of the tint which printed out from the exposure. The same exposure may be trusted always to give the correct print from a negative of the density which would print that tint, if tested with P.O.P. as for carbon printing. The figures in the meter are so arranged that, by moving the proper

scale, the exposures for any required size of enlargement are also indicated with equal accuracy. It must be understood, however, that this accuracy can only be assured by using apparatus of the kind indicated, and by making certain, when adjusting the light, that the sharpest possible image of the source of light is thrown upon the enlarging lens. This caution is the more necessary, as it will be found that the light may be moved a considerable distance from the point where that condition is satisfied, without affecting the even illumination of the disc, though probably with some diminution in the intensity of the illumination. The latter, of course, might make a material difference in the time of exposure.

JOHN NIXON.

## EASTMAN KODAK COMPANY, OF NEW JERSEY.

THE report of this company for 1907, and balance sheet as at December 31 last, have just been issued. The results of the year exceed the previous records of the company. The net profits, after making provision for depreciation on buildings, plant, and machinery, and after writing down the investments by \$61,856, as well as setting aside a sum of \$154,639 to augment the special fund for the renewal of plant, amount to \$1,291,839, as against \$1,013,546 for the previous twelve months—an increase of \$278,293.

Dividends of 6 per cent. upon the preferred capital and 25 per cent. upon the common have been distributed, leaving \$206,996 to be added to the undivided Surplus Fund, increasing it thereby to \$1,152,199. In addition to this surplus there are now special reserves amounting to \$500,535, making the surplus profit a total of \$1,652,734.

The earning power of the company shows a steady increase, as will be seen from the following statement of annual earnings:—

Year ending December 31, 1895	\$49,656
" " " " 1896	122,676
" " " " 1897	185,232
" " " " 1898	243,232
" " " " 1899	335,919
" " " " 1900	465,816
" " " " 1901	517,347
" " " " 1902	564,455
" " " " 1903	606,740
" " " " 1904	688,484
" " " " 1905	827,610
" " " " 1906	1,013,546
" " " " 1907	1,291,839

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between March 30 and April 4:—

- CINEMATOGRAPHS.—No. 6,983. Improvements in optical lanterns for cinematograph displays. George Robson, 21, Rochdale Road, Leyton, Essex.
- PRINTING.—No. 7,001. Improved printing device. Charles Jennings Hillman, 149, Strand, London.
- CAMERAS.—No. 7,061. Improvements in photographic cameras. George Lloyd Moore, 35, Temple Row, Birmingham.
- FILMS.—No. 7,087. Improvements in photographic films. Frank Wordsworth Donisthorpe, 5, Southampton Street, Strand, London.
- PRINTING FRAMES.—No. 7,098. Improved frames for photographic printing. George Donaldson, 37, Chancery Lane, London.
- CINEMATOGRAPHS.—No. 7,134. Improvements in apparatus for displaying cinematograph films. Percy Harold Boggis, 57, Chancery Lane, London.
- CAMERAS.—No. 7,159. Improvements in photographic cameras. Harry Wilson Goulding, 26, Park Road, Moseley, Birmingham.
- MICRO-CINEMATOGRAPHS.—No. 7,306. Micro-cinematographic apparatus. Frederic de Mare, 72, Cannon Street, London.
- DISHES.—No. 7,344. Improvements in trays or dishes for photographic purposes. John Ernest Gray, 17, St. Anne's Square, Manchester.

- CAMERAS.**—No. 7,346. Improvements in cameras. George Dawson, 115, Gorton Road, Reddish, Stockport.
- CINEMATOGRAPHS.**—No. 7,414. Improvements in cinematographs. Claude Marie Guillet, 11, Southampton Buildings, London.
- CAMERAS.**—No. 7,512. Improvements in photographic cameras. Joseph Gaut and Harrington and Co., Ltd., 46, Lincoln's Inn Fields, London.
- COLOUR-CINEMATOGRAPHY.**—No. 7,514. Improvements in apparatus, for living pictures on the multiple-colour method. Christian Peter Christensen, 1, Queen Victoria Street, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

- PLATE-HOLDERS.**—No. 3,179. 1908. The invention relates to photographic plate-holders, more particularly to holders for plates, the sensitive coatings of which have to be exposed through the body of the plate, as is necessary in the case of some processes of colour-photography. The invention consists in arranging in the holder a movable frame, into which the plate is inserted, and a device which tends to thrust this frame against the inwardly projecting flanges fixed to the front part of the holder, so that when the

Fig. 1.

shutter inserted between the flanges and frame is withdrawn, the plate and frame are thrust forward, and the sensitive layer is thus brought into the proper position for exposure.

An arrangement is made whereby the plate can be caused to slide from the open holder without allowing the movable frame to slide out as well.

The outer frame of the holder is marked 1, and has flanges 2 forming guides for the shutter 3; 4 is the slidable back of the holder. The plate-frame which forms the essential feature of the invention, is marked 5. It is provided externally with recesses 6, into which extend the points of screws 7. The photographic plate in the frame 5 is designated by the numeral 8; 9 being a spring-plate, which is thrust in the usual manner against the photographic plate by springs 10 fixed to the back of the plate 9.

The holder is used exactly as the ordinary holder. After the opening of the holder by withdrawing the slide 4, the plate is placed in the frame 5, and the holder is re-closed. For exposure, the

Fig. 2.

shutter 3 is opened, and re-closed after the exposure. The plate inserted into the holder does not, however, remain stationary on the withdrawal of the shutter, as in ordinary plate-holders, but is thrust forward against the flanges 2, together with the frame 5, until the front surface of the latter abuts against the inner surfaces of the flanges 2. When the holder is tilted, or laid down, and opened, so that the plate can slide out, the screws 7 retain the frame 5. Optische Anstalt C. P. Goerz Aktiengesellschaft, 44-46, Rheinstrasse, Berlin-Friedenau.

- PLATE-HOLDERS.**—No. 13,601. 1907. The object of this invention is to dispense with the slide which is placed before the photographic plate in a camera, and which has to be pulled out before the camera can be used, and to provide a frame or envelope for carrying the plate, by which means plates can be placed in the camera in daylight. The back of the dark slide may be hinged in order to allow of the introduction of the envelope. In the dark slide, according to one form of the invention, are two bars, which

are caused to move to and fro in slots in the sides of the slide by means of cords or chains passing over pulleys or sprocket wheels at the top and bottom of the slide, or the bars may be moved by roller-blind mechanism. To these bars is detachably secured a curtain, which forms part of the envelope, one bar being secured to the curtain at the front of the envelope and the other behind so that by turning a shaft the curtain may be withdrawn from before the plate. Colonel Archibald James Erskine, Holly Bank, Mannamoad, Plymouth.

- PANORAMIC CAMERA.**—No. 19,779. 1907. This invention relates to the class of instruments known as panorama cameras, in which the film is arranged in the form of a cylinder, and the lens adapted to rotate about the centre of such film cylinder, so that the whole horizon may be projected on to the film.

In cameras of this type, as hitherto proposed, the film cylinder is arranged with the sensitised side at the outside, and the outer casing of the camera carrying the lens is adapted to rotate about the centre of the film cylinder, with which construction the lens projecting from the side of the outer casing, is liable, when rotating, to contact with the body of the operator, and be stopped and consequently over-expose a portion of the film. The present invention provides a camera in which this disadvantage is overcome. An important feature of the invention consists in arranging and rotating the projecting apparatus within the film cylinder, an arrangement allowing the lens to be arranged wholly within the area of the camera and the outer casing to be kept stationary, which is also an important advantage over other cameras heretofore proposed. A further feature of the invention is the provision of stops, adapted to close the shutter at any desired point of the circular path of the projecting apparatus, whereby a picture of any desired length may be taken.

Other features of the invention are the means for varying the time of exposure to suit prevalent conditions, the means for indicating when an unused portion of the film is placed in position to be exposed, and the shutter operating and locking mechanism. The twenty-three drawings are necessary for the proper explanation of the apparatus. William Arthur Case, 1,145, Hayes Street, San Francisco, Cal., U.S.A.

- CINEMATOGRAPHS.**—No. 14,058. 1907. The invention relates to an improvement of the apparatus described in Moy's patent, No. 25,625, 1897, and consists of a projector or camera in which the feeding mechanism is operated by a cam. The cam shaft is driven by means of an epicyclic train. Ernest Francis Moy and Percy Henry Bastie, Greenland Place, Camden Town, London, N.W.

- MOISTENING CINEMATOGRAPHIC FILMS.**—No. 562. 1908. The invention is an apparatus for preventing the drying and cracking of the cinematographic film during projection. The claims are: (1) Means for moistening cinematographic bands or films, characterised by the application of steam from hot water upon the gelatine of the band or film whilst the latter is being unrolled. (2) Apparatus composed of a boiler, a suitable lamp, surrounded by a protective cover, and a metal or rubber tube, of which the free end is placed under the moving band or film, the distance between the two being lessened as the rapidity of travel of the band increases. Eugène Louis Amédée Lertourné, 2c, Rue Pavée, Rouen.

### New Trade Names.

- WAFER.**—No. 300,023. Photographic cameras included in Class photographic plate-holders or slides and photographic shutters. The Thornton-Pickard Manufacturing Company, Ltd., Camera Works, Broadheath, Altrincham, Cheshire, photographic apparatus manufacturers. January 30, 1908.
- LUXEPIA.**—No. 300,718. Photographic printing papers and sensitized photographic cards. Maurice Sinay Berger, 9, Clevedon Mansions, Lissenden Gardens, Highgate Road, London, N.W., photographic chemist. February 24, 1908.
- PRIMOIL.**—No. 300,964. Photographic papers. John J. Griffin and Sons, Ltd., Kingsway, London, W.C., photographic apparatus and paper manufacturers. March 3, 1908.

### Notes on Cleaning Old Daguerreotypes.

Little alcohol absolute (writes Mr. C. Welborne Piper in "The Photo Photographer") was first flowed over each slide, about a being sufficient in each case, and the plate was then immersed under a gently flowing tap. In two or three minutes its retained the water when drained, and it was then immersed in a cyanide solution (10 grs. to the pint) for ten minutes. After the hypo bath, the plate was rinsed under the tap for about half a minute, then placed in an empty dish and treated with a cyanide solution (10 grs. to the pint of distilled water) until the stains practically disappeared. The cyanide attacks the copper plate, it was thought best to gently pour the solution on and off the plate, but in obstinate cases the plate was left in the cyanide solution for a few minutes. Its removal from the copper is very slight, and possibly of no consequence to the image; but I thought it advisable to frequently replace the cyanide with fresh solution, and certainly found that this considerably quickened the cleansing process. In some of the worst cases the stains were very obstinate, and I repeated the alternative treatment of hypo and cyanide several times. Finally, however, I came to the conclusion that this repetition had little if any effect, and that even though faint traces of brownish stain could still be detected in the wet cleansed image, such traces almost completely disappeared in the drying process. The wet slide does not in any way look very clean, but drying produces a wonderful change.

## New Books.

tochemie und Photographie." By Dr. Karl Schaum. Part I. A. Barth, Leipzig. 1908. Mk. 10.

This work forms the ninth volume of Professor Bredig's "Handbuch der Angewandten physikalischen Chemie," and as such it is not that of a text-book, but rather to give a critical summary of knowledge in its branch of science. Too frequently in such books "the criticism is wanting, and a mere compilation results, instead of a system in which lessens its value even as a source of information. No such defect is to be urged against Professor Schaum's work, the first part of what promises to be the most complete treatise on the first part of the sciences, photo-chemistry. The portion of the book which deals almost entirely with the physical aspect of the subject and measurement of radiant energy. The conversion of heat into radiant energy and the energetics of radiation, starting from Planck's law, are admirably condensed, and a good description of the practical methods in this region. The evolution of the theory of radiant energy, otherwise one would wish for more attention to the work of Stewart's pioneer work. The questions, to which now a quantitative answer is possible, were, "How does the energy of a heated body depend upon the latter's nature and temperature? And, further, how does the spectral composition of radiation depend upon the same?" One important practical result from this inquiry is the method of optical pyrometry, and it is noted that, by the application of the laws of radiation, it is possible (1) to measure much higher temperature than by gas or thermometers, (2) the temperature of extra-terrestrial and unattainable bodies may be determined.

The whole question of photometry is dealt with in a very complete and systematic fashion, being preceded by an excellent discussion of the sensitivity of the eye, both as regards colour and intensity, and of the laws of colour measurement and mixture. In particular the phenomenon of the eye is fully discussed, and an explanation suggested based on different functioning of the rods and cones. The methods and of "total" photometry include a useful table of definitions. The section on spectrophotometry is rather

brief, considering its importance, both for photochemistry and photography, but much of the matter is dealt with under other heads. The final section of this part deals with the principles and methods of lighting technique, and gives a very adequate survey of the progress made here. It is pointed out that absolute general rules for the valuation of a light source cannot be set up, according to conditions one or another quality may determine its value. But beside the valuable résumé of facts he gives, Professor Schaum has sought to clarify the medley of definitions which are used with respect to the efficiency, economic, and other values of artificial sources, and useful tables exhibiting the comparative costs, efficiency, life, and so forth are included.

The whole work is well illustrated with pertinent curves and diagrams, and though the treatment is throughout from an exact and mathematical standpoint, this is inevitable in a treatment of the subject designed for the specialist.

S. E. SHEPPARD.

"Das Kopieren bei Elektrischem Licht." By Baron von Hübl. (Halle: W. Knapp. Mk. 1.80.)

In this volume Baron von Hübl has collected and condensed the articles on electric illuminants which appeared in a German contemporary last year, and were translated to a large extent in our own columns. The book deals with the areas of equal illumination given by various types of arc and other lamps, and in general gives the results of the author's measurements in respect of such important matters as the value of reflectors, the effect of length of arc, etc. Though hardly a volume from which the printer or portraitist by electric light can derive much assistance, the information in it is of a kind which should be considered by makers of apparatus for these two classes of workers and the collection of the articles in book form is therefore a task for which we may be grateful to author and publisher.

### CATALOGUES AND TRADE NOTICES.

"CAMERA HOUSE JOURNAL" in its current issue gives photographers the benefit of the weather forecast for the coming season, as set forth by Messrs. Butcher's meteorological department, and intimates at the same time, for the guidance of the dealer, the make of camera which will be in demand. But although tropical weather, with a consequent demand for the "Tropical Excelsior," is predicted, the firm provides for possible disappointment by giving particulars of other types of their well-known cameras suited to a more temperate condition of the atmosphere. An interesting feature of this issue is a coloured inset, showing examples of a series of mounts of which Messrs. Butcher make a speciality, particulars of which may be obtained from Camera House, Farringdon Avenue, E.C.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, APRIL 17.

United Stereoscopic Society. Excursion to Rye and Winchelsea.

MONDAY, APRIL 20.

Harrow District Photographic and Scientific Society. "Gum Bichromate." J. Brown.

Stafford Photographic Society. Annual General Meeting.

TUESDAY, APRIL 21.

Royal Photographic Society. No Meeting.

Epsom and District Literary and Scientific Society. "Carbon Printing." Illingworth & Co.

Hackney Photographic Society. Questions and Answers.

Worthing Camera Club. Annual Meeting.

WEDNESDAY, APRIL 22.

South Suburban Photographic Society. "Portfolio and Print Criticism." Annual General Meeting.

Woodford Photographic Society. "Choice of a Printing Process." J. P. W. Goodwin.

Croydon Camera Club. "Elementary Photographic Chemistry." W. H. Smith.

THURSDAY, APRIL 23.

Handsworth Photographic Society. "The Production of Cloud Negatives." Demonstrated. F. Greenway.

North London Photographic Society. "Pictures in Holland." F. W. Fincham.

Richmond Camera Club. "Enthusiasts." R. & J. Beck, Ltd.

Rodley, Farsley and Calverley District Photographic Society. "Field Work." H. Crossley.  
 London and Provincial Photographic Association. "Polarised Light." J. Brignshaw.  
 Liverpool Amateur Photographic Association. "Afar in the Fatherland." W. L. F. Wastell.

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

The usual monthly meeting of the General Committee was held on Friday, 10th inst. Present: Messrs. H. A. Chapman, J.P., Alfred Ellis, S. H. Fry, L. Langfrier, A. Mackie, D. Prodder, C. H. Skillman, Lang Sims, and R. Fellows Willson. Mr. H. A. Chapman, J.P., president, in the chair.

Mr. Alexander Mackie was re-elected hon. secretary, and Mr. Lang Sims hon. treasurer for the ensuing year.

A letter was read from the manager of "The Exhibition Herald," the organ of a Missionary Exhibition to be held this year in London, in reply to a protest made by the Association against an advertisement of a misleading character of cheap enlargements. It was to the effect that the advertisement complained of had been inserted without reference to the authorities of the exhibition, and would not be allowed to appear again.

The solicitor's account for costs in connection with defending two cases in the Pocklington (Yorks) County Court, brought by a free-press portrait firm, was passed for payment.

The question of the representation of the Association and of the interests of professional photography at the conference to be held at Berlin in October next for the revision of the terms of the Berne Convention with regard to international protection of copyright was discussed, and it was agreed to refer the matter to the Copyright Sub-committee.

The case of a photographer who had made unauthorised use of the name of the association in threatening proceedings was discussed and a certain course decided upon.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held April 9, 1908, Mr. H. Snowden Ward in the chair. Mr. C. L. Finlay had been announced to give a demonstration of the Thames colour screen plate. Owing to difficulties due, it was stated, to the British workman, the demonstration, so far as it consisted in the exhibition of results, did not take place, but Mr. Finlay said that the plates would be on the market in fourteen days from that evening.

In the new plate, he continued, advantage had been taken of the half-tone screen in the preparation of the coloured ground or screen. The first colour was laid upon the glass at an angle of 45 degrees, the second was laid on the top of this, also at the same angle, whilst the third was so used that it filled in all the spaces. Thus there are no white spots, and no other filling was needed, and no black or other colour entered into the making of the plate beyond that of the screens. At this point the actual colour-coated plates were projected on to the screen, and although the 3-inch square plate was thrown up to some 7 feet, the grain was scarcely perceptible to those within some 5 feet of the sheet, whilst at the end of the room it could not be detected at all. When a double and triple coated plate was projected the colours were easily seen, and, said Mr. Finlay, these were from a screen of 120 lines to the inch. For the scientific worker it was intended to use a much finer screen than this. The ultimate result that was being aimed at was that of being able to print the coloured positive, and the grain would here again be of a much finer nature. The emulsion was one specially adapted to the work, and a special compensating filter would be issued with each box of plates; this would be of a very pale yellow, and in many cases it would not be necessary to use a filter at all.

Mr. O. S. Dawson, on being called upon to say a few words, added that the next stage was that of being able to produce the coloured positives on paper in one printing. He thought that a coloured transparency process was doomed to a short life, but with the plate under notice it would be possible to obtain coloured prints by the aid of Dr. Smith's Uto paper, and he passed round prints upon this paper that gave great promise.

Rev. F. C. Lambert asked if the two colours, red and green, were the circles and the blue the filling colour. The reply to this was that it was so. In reply to a question as to the plates being faster than the Autochrome, Mr. Finlay said that it was to be expected that the speed would be much greater; further, as each box of plates

would have its own filter, any slight variations in the emulsion would be compensated for, the speed of each batch would also be given, and would also the time of development. As to the absorption of the filters, Mr. Finlay said that this was abrupt. Not the least sign of filling had been found, and the colours were put down by a photographic process and held in a colloid; the working of the plates was develop, reverse, and fix. The results would stand great enlargement in the lantern.

Dr. Lindsay Johnson asked if the red, green, and blue dots were the same size. As to the pale yellow screen, the Lumière one was of a warm pink or orange colour. Why could this be done away with? How was the blue held back? Mr. Finlay said that the red and green dots were the same size, and the rest was filled in with blue; the reason a pale filter could be used was because the dyes passed a large amount of light, of their own colour, but cut off the blue and other rays, and the emulsion was so sensitive to the red and green that it thus caught up the blue.

Mr. Lambert asked the relative size of the dots compared with the Autochrome plate, and Mr. Finlay said that they were from a 250-line screen, and would thus be larger.

Mr. W. E. Debenham said that the dot must be large enough to give white light, and Mr. Malby said that his trouble with the Lumière was the rendering of white, and he was anxious to know if one might expect to be able to obtain pure white on the new plate. Mr. Finlay stated that the plate would give as pure a white as could be expected when dealing with colours. What Mr. Malby complained of was, he said, that the whites had the appearance of mother-of-pearl in the plates he had mentioned, and Mr. Finlay said that the more even distribution of colour would remedy this.

Mr. Bayley thought that Mr. Malby was too severe a critic upon his own work, as he had seen it, and thought that the whites were all that could be desired.

Mr. Walker said that the Joly process gave a pure white, and this was undoubtedly due to the straight lines used, and he thought that the new plate would gain in this, owing to the rulings.

Dr. Johnson thought that the degraded whites were due to the light being thrown back from the black cardboard. He now used black velvet, and had no trouble in this respect, as its use gave much more brilliant colours. His trouble was to get a good black.

In reply to a question as to the permanency of the colours, Mr. Finlay said that everything had been done to make them permanent and that they were formed into lakes with this idea.

Mr. Snowden Ward, in proposing a vote of thanks, said he had pleasure in offering the thanks of the meeting to Messrs. Finlay and Dawson. This was carried with acclamation.

The hon. sec., Mr. Ernest Human, here announced that he had made arrangements for another night on this subject, possibly in June, when the whole proceeds of developing, etc., would be done in the room and results shown. The exact date he would announce later in the photographic press, and he asked visitors to carefully watch the press for it.

A series of slides on the Autochrome plate by Mr. Malby were then shown, and when one says that these were up to Mr. Malby's usual standard they have the highest praise that it is possible to give to any slide work.

SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.—On Wednesday, April 8, an able and interesting lecture on "Recreations with an Enlarger" was given by Mr. J. Nixon, the hon. secretary of the society. With him was associated Mr. J. L. Savage, who proved an able demonstrator. Mr. Nixon stated that his audience would find his lecture most unorthodox. He then set out to prove that the common dictum that correct exposure for enlarging, by day or artificial light, must be found by "trial exposure" is untrue and provocative of waste in time, patience, and materials, though undoubtedly profitable to the "makers"—that is, it was possible to reduce exposure to a system as simple and certain as finding the exposure necessary for a "plate." A meter of his own construction was then passed round, and Mr. Nixon demonstrated, by means of a skeleton enlarger and the blackboard, the method of arriving at the mathematical formula by which it was constructed. Exposures were at this stage made by Welsbach gas mantle, and the results proved the meter a success. A discussion followed, during which it was suggested that the meter should be put on the market. It was stated that with stamper plates this meter would be useless, and also that the meter was

signed for use with oil or gas mantle illumination, and would not be satisfactory with arc, Nernst, or similar illuminants giving an image at the lens smaller than its working aperture. On the motion Mr. Percie Edwards (chairman) a hearty vote of thanks was accorded to Messrs. Nixon and Savage. The full text of the paper given on another page.

**SUTTON PHOTOGRAPHIC CLUB.**—The winter session of this society, which has never been more active and prosperous than it now is, after twenty-five years of photographic propagandism, was brought to a conclusion on April 10 by an ably handled address upon the relationship between "Exposure and Development," by Mr. H. W. Lane, in the course of which he touched upon many points that even seasoned photographers are at times apt to overlook. For instance, he emphasised the difference of time which is called for by exposing to a pictorial aim and that which suffices where the object in view is merely to obtain some kind of a record, such as, for instance, is usually met in the photographs of foot races, etc.; while in the latter instance very presumably little beyond the high lights are registered. In the former it is requisite to impress the plate with a developable image of the details verging on the deepest shadows, which reason the determination of a normal exposure must, in large measure, depend upon whether or not pictorialism is the aim and aim in view. Comparing the respective advantages of anemometer and exposure tables, he said that those who occupied themselves in taking mixed subjects would find that the difference of exposure due to the class of subject was far more variable than changes in the actinic powers of daylight, which, as a rule, would be very closely gauged by aid of tables or an exposure card. Speaking on the errors in exposures due to imperfections and shutters, he stated that, although he usually tested his shutters himself, on one occasion he sent a shutter to a firm to be tested, and received back a certificate showing that all the speeds marked on it were twice as fast as the shutter actually worked. Being doubtful of this report he immediately sent the same shutter to another firm, who sent him back their certificate stating that the speeds marked on the shutter were only half as fast as the actual shutter speeds. As regards development, Mr. Lane considered raising the temperature of the developers to be more efficacious in producing detail than in increasing the amount of accelerator. He approved of "time" development, and showed sets of negatives which had received exposures varying amounts which developed by time for an identical period of time, and produced prints which were nearly identical in their gradation. Subsequently the chairman of the club, Mr. Hector Maclean, showed and described two new patterns of view finders—viz., the "Sellar," which assesses the useful power of showing a brilliant image, which is only right way up, but also right way about, and "Watson's" finder and telemeter, which is so constructed that it can be used as a direct view or as a "reflector" finder, and which is also fitted with an ingenious attachment by means of which it is possible to measure the distance from the benolder of any particular object.

**PROYDON CAMERA CLUB.**—Years ago public lantern shows used to be a feature of the club's syllabus. These consisted of a series of slides of varying degrees of excellence, passed by a Selection Committee, but totally disconnected with each other, and practically devoid of dialogue. Notwithstanding this they were well attended by members and friends, and formed a source of profit, as well as entertainment. Interest, however, gradually waned, and eventually they had to be abandoned for lack of support. The death of the lantern as a means of public attraction was held to be due to the advent of the cinematograph. That the causes operating were more within than without seemed to be proved by a lantern lecture given by Mr. W. L. F. Wastell last week, entitled "Afar in the Fatherland," giving an irresistibly humorous as well as interesting account of a day trip up the Rhine and Moselle. The "Walrus" was gay and lively in rapid succession. In some cases the alterations were perhaps rapid, for now and then a member, possibly of Scotch extraction, caught some of his more subtle jokes rather late, and burst into hearty appreciative laughter, just as the lecturer, with a fine attempt at solemnity, was breaking out into poetry of a pathetic kind. One interesting scientific fact, bearing on evolution, was elicited during the evening. The modern walrus, whilst undoubtedly an authority on the various Rhine wines and lager beers, seems to be losing his aquatic habits; the recollection of an accidental slip from a pre-

historic plank-bridge into what should have been the refreshing water underneath, being spoken of with considerable distaste. The slides illustrating the lecture were really first-class, many of them exceedingly beautiful. They included some fully authenticated and unique photographs of early German dragons, breathing fire and fury, and chivalrous knights of old, heavily goloshed and mackintoshed, with unsheathed umbrellas, ever ready to strike a blow on behalf of right and virtue. In the course of the evening the president (Mr. J. M. Sellors) gave a short exposition of the new Donisthorpe process (fully described in our pages last week), which attracted much attention. A new roll-film is also promised coated on black paper. Mr. E. A. Salt suggested white paper would be more advantageous; it was common knowledge that this as a support, in effect added to the speed of the emulsion, the reflected light coincided with the image, and halation in the ordinary sense was absent.

## Commercial & Legal Intelligence.

**LEGAL NOTICES.**—A first and final dividend of 2s. 1½d. in the £ is to be paid at the Official Receiver's office Liverpool, on April 13, in the bankrupt estate of James Shaw, photographer, residing and carrying on business at 4, Bridge Street, Southport, Lancs.

A meeting is to be held at Luton on May 6, of the creditors of Arthur Joseph Anderson, photographer, of 37, Wellington Road, Luton; 36, High Town Road, Luton; and 7, High Street, Leighton Buzzard, all in Bedfordshire.

## News and Notes.

**DARWEN PHOTOGRAPHIC ASSOCIATION.**—The secretary of the above is now Mr. W. Edge, 33, Radfield Avenue, Darwen (vice F. Dearnley, resigned).

**MESSRS. GRIFFIN** are holding a sale of apparatus, and such materials as mounts, at their premises in Kingsway, London, W.C.

**OLD MASTERS IN GERMANY.**—A correspondent writes:—"The exhibition of old English masters in Berlin, which has lately taken place, was considered on all hands to be a great success. It was held under the auspices of the Berlin Academy, and opened by the Kaiser in person. Apart from the fact that never before had any opportunity of seeing a representative collection of English pictures been afforded to Germans, there was also the international aspect. It was considered as a distinct help towards an improvement in Anglo-German relations. Yet even here the course of international love has not run smooth, and the Berlin Photographic Company seems to have been the offending rock. It appears that this company obtained the permission of Herr Kampf, the president of the Academy, to publish a souvenir catalogue, in addition to the official catalogue, which had been sanctioned by the English lenders. Many of these masterpieces have not been reproduced before, even in England, an omission which should be speedily remedied. But the owners of the pictures resented this free-handed action on the part of foreign borrowers. The reproductions were to be tastefully got up and sold by the Berlin Photographic Company at a high price, while the Academy were to receive forty copies as a free gift in return for the rights of reproduction. It would indeed be an anomalous state of affairs should the company obtain the copyright of English pictures and so be in a position to prevent their reproduction later on in England. One result of this friction has been the withdrawal of many exhibits from the collection previous to the removal to Copenhagen. So the Danes have had to suffer for their neighbour's shortcomings—or rather fargoinings."

[Our correspondent overlooks the fact that the foreign copyist could establish copyright only in his copies of the paintings. He could not restrain the issue of reproductions of the painting in England.—Eds. "B.J."]

**WELLCOME PHOTOGRAPHIC CLUB EXHIBITION.**—On Saturday in last week the seventh annual exhibition of the Wellcome Photographic Club at the Wellcome Club and Institute, Dartford, was opened by Mr. H. Snowden Ward, F.R.P.S. The chairman, Mr. H. C. Sayer,

briefly drew attention to the favourable condition, both financial and otherwise, of the club. He also referred to the indebtedness of the members to their president, Mr. H. S. Wellcome, for the splendidly equipped dark-rooms, and announced that in future the committee intended to do more to encourage technical photography.

Mr. Snowden Ward made a highly interesting and instructive speech. He congratulated the members on the excellence of the exhibits, which he considered highly creditable to a club that relied wholly upon the work of its own members, and which he said would compare favourably with the members' class of any club in England. In referring to the aims of artistic photography, he emphasised the importance of the elimination of the non-essential, and the need for more concentration in photographic work. He then formally declared the exhibition open.

The following awards were made:—Bronze casket, for the best picture in the exhibition, "Melton Meadows," Mr. W. H. Fowkes. In Class A, for members who had previously received an award in an open competition, three pictures received honourable mention: "Tugging," Mr. H. W. Lane; "Sunset," Mr. S. F. Morgan; "On the River," Mr. F. C. Starnes.

In Class B, for members who had not previously received an award, there were two bronze plaques, presented by Mr. G. E. Pearson, general manager, and Dr. Jowett, works manager. First plaque, "On a Kentish Common," Mr. I. J. Gash; second plaque, "Street Scene, Dinan," Mr. E. G. Price. Honourable mention: "An Alpine Scene," Mr. R. E. Jackson; "Fading Tints of Western Skies," Mr. H. Hamlin.

The exhibition included a large and excellent loan collection of colour photographs, including some of the best examples of the work of Messrs. Henry J. Comley, R. Child Bayley, John H. Gear, J. A. Sinclair, and others.

## Correspondence.

\**We do not undertake responsibility for the opinions expressed by our correspondents.*

### THE PORTRAIT POSTCARD.

To the Editors.

Gentlemen,—*"Audi alteram partem"* is oftentimes a saying well worthy of attention, and so I wish to say a few words in reply to "Indenture" and others. I have been employed by a London photographer to retouch his special negatives. I have lectured on printing processes before an advanced London club. I have had my portraiture compared with Baker Street work, to the disadvantage of the latter. And, I confess it boldly, I am merely "something in the City," and practice photography in my spare time. The crux of the whole matter is this: That the ordinary professional is not worthy to have apprentices at all. What does the ordinary youth who has been indentured really know about Art? How often has he been to the National Gallery, the Tate Gallery, or the Wallace Collection to study—lovingly—the portraiture there? Professional photography has been regarded far too long merely as a trade, but the public—at least the educated public—is now beginning to want an artistic picture as well as a photograph. I fancy that Miss Alice Hughes, H. Walter Barnett, J. H. Gear, William Gill, etc., are not complaining much about the present slump in things photographic. As regards postcards, I quite agree with the opinion of the majority of your correspondents. Good work is worth paying for, and the man who does a good business in carbon, plat., or C.C. cabinets, ought, if possible, to resolutely refuse such orders.

BRAINS.

To the Editors.

Gentlemen,—Allow me to say how pleased I am that you have opened your columns to a discussion of the abominable portrait postcard nuisance. Surely something can be done to prevent prices being cut so low. Here there are several doing postcards, taken with a half-plate, for 2s. 6d. a dozen, and I have sitters come and expect two positions, and groups, including dogs, etc., and want proofs for that price. When I point out to them how impossible

it is they reply that So-and-So only charges 2s. 6d. a dozen, and gives re-sittings if necessary. The only remedy I can see is the very sensible one of a £10 licence, suggested by one of your correspondents.

I may say I never show a portrait postcard or quote prices, and when postcards are insisted on I always try and introduce something else. In spite of that, some weeks half my sitters are postcard orders; many those who used to have cabinets.

Another thing here is the competition from gardeners, coachmen, postmen, and hosts of other trades, who have half-plate cameras doing work and charging just a trifle over the cost of material. Their victims have since paid for the work, put up with the quality, and cannot afford to go to a professional man and have it done again. Many times I have had enlargements done by these men, brought to me to try and improve (!), as they were not satisfactory, and the explanation given is that they were done by an amateur.

The other day an amateur, in a gushing moment, told me he had photographed a family group of some friends of his. On showing them the proofs they ordered a dozen, and after sending the prints and hearing nothing about paying he politely suggested that it cost him something for material. They told him "if it was payment he was after they should not think of doing so, as the prints were not worth it, and they quite thought he was giving them as a present." I told him it served him right, and gave him a little homily about sticking to his own business and letting other trades and professions alone. He is a man with a fair salary and has no need to cut other people's work.

Now this kind of thing would be put to an end by a photographer paying a licence. We hear of no one grumbling that an auctioneer should have to have a licence, and why not photographers? Surely the P.P.A. could do something in the matter.—Yours faithfully,

RUSKINS.

To the Editors.

Gentlemen,—In this city (Manchester) almost every studio (except the ultra-fashionable) exhibit postcards in their show-cases usually at 2s. 6d. per dozen, and rarely, if ever, higher than 3s. a dozen. The public have realised that a postcard is scarcely smaller than a cabinet, and is usually quite as good. In the principal residential suburb here, where there are no high-class studios (these are all in the "city," which is quickly reached by car), a stationer and newsagent has a case full of postcards of groups, private houses, wide and without figures, and portraits taken in the garden. These are not retouched, being evidently amateur work, and the figures are kept small, but the work is clean and brilliant. This man offers to attend to take such portraits at 2s. 6d. per dozen. Of course, he does not depend on this for his living, but how can a professional compete with such absurd prices unless he could keep a man's time filled with that work only?

Then there is a man who touts the shop fronts and sells the cards at 2s. per dozen. A customer told me mine were six times as good as the tout's work, but would not pay more than 2s. 6d. for the cards! When a customer wants a reduction for a locked it is invariably a "stamp photo" I am asked for, and the price is expected to be accordingly. This seems the age of the "very dear" or the "very cheap" photography (the latter not always nasty), and it takes a large capital to make money at either kind.—Yours, etc.,

Manchester.

April 13, 1908.

To the Editors.

Gentlemen,—I have followed with interest the numerous letters re postcard photography, and, while deploring the existence of many things connected with the profession, I should like to say a few words in defence of at least one of the so-called "postcard fiends."

Thirty-six years ago I was apprenticed to photography (a date I have no doubt when some of those who are calling out about their rights and wrongs were not born), and for several years I worked as an assistant in some of the best studios. About twenty-one years ago I opened a business for myself in a small country town, about twenty miles from Birmingham, and for several years I did a fairly good trade with views of the town as well as portraiture; but with the advent of the amateur, and later with picture postcards, I found

portion of my income practically disappear. Then came the postcards, which commenced their existence in the larger, and with great facilities offered by the railway companies in the way of half-day trips three or four times a week to these centres I found that my portrait business was going away of the view portion. What then, was my position?

With a large family to provide for it was no use sitting down and crying over my losses; I had to try and with the prices charged in Birmingham and elsewhere, and to put time with the cheap man, who was canvassing for customers at every door. Even then I was unable to get a living, so have I to move to a large town, where I am advertising postcards at a dozen, and, although the work is good, yet even at that I cannot get sufficient customers to keep myself and family stable. Now, I should like to ask those successful ones who so glibly of their dignity, their fair prices, and £10 licences, whether I am not justified in trying to get even a part of a living even to do postcards at 1s. per dozen if by so doing I can show it, or am I to sacrifice myself and family for a principle, or barred from following a profession to which I was apprenticed to which I have worked for thirty-six years, because, through no of mine, I have been unsuccessful, and could not afford to do a year for a licence? I have vainly tried to obtain a situation, though I have undeniable references as to my character, tell me I am too old (48), so that by their way of reasoning it is nothing but the workhouse or some such kindred place that "Play" and others of your correspondents would condemn the successful ones to.—Yours faithfully,  
ONE OF THEM.

To the Editors.

Gentlemen,—Just fancy! A photographic artist, value £10 per an! "Here, Johnnie, run down to the post office and get me a licence for 'Carlo' and one for myself. Here's £10 8s., and the change back." I do not see any remedy for the present of the profession. This is an age of cheapness; the public must be met. There may be a few who cater for the well-to-do and are in a safe position, who can afford to hold aloof from "cheap" work, but they are a very small percentage. What must be the majority do? If they refuse to supply the public it will be better cut to the final than trying to make the best of a bad and doing postcards—good postcards.

My policy of telling your clients "You don't care a hang whether made or not" is all very well if you do not happen to have a who tells him that "They will last for ever and a day," and does equal or better work. Keep up the standard, even if the "fiends and vultures" will not do much harm, but I suppose they must live.

Suppose a man, bricklayer or navvy, loses his employment. He has possibly dabbled a little with a camera as a hobby. Can you advise him for trying to keep body and soul together by using his knowledge and turning it to advantage? There are many who have been forced into it. Do not let us condemn anyone for trying to earn an honest penny by any device in such a comely age. Perhaps there are some photographers who would be against doing a little bricklaying in order to fill their empty pockets; in fact, we all do a little, if only by repairing the studio ories, etc., perhaps doing a bit of plumbing or painting, just to "so much."

Expensive portraits are a luxury that few people can afford. They are difficult to pay from 10s. upwards for something in the nature of photographs. Most wages will not run to that amount, therefore the "Lord High Artist" suffers, and must adapt himself to circumstances or take the only alternative.

My own case is like most others. I have come down to postcards, but they do not pay my rent, etc., so am trying to obtain a licence again; but from replies received the profession seems to be in a very bad state, does not seem able to pay a married man's wages away to a trade firm who do enlargements for a few pence, or print, glaze, and trim postcards at very little per 1,000. There is any remedy the whole competitive system will have readjusted.—Yours, etc.,  
A VICTIM.

## Answers to Correspondents.

\**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

\**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

E. J. Moorhouse, 102A, King Street, Egremont, Cheshire. *Photograph of the Rev. T. Price Davies of Liscard, Cheshire.*

R. Duncan, Ayr Street, Catrine. *Photograph of Catrine Cotton Works. Twin Iron Wheels.*

F. C. MacMahon, 23, Academy Street, Inverness. *Photograph entitled, "The Last Parade of Volunteer Forces, Inverness, March 31, 1902."*

W. F. Gould, 22, Milsom Street, Bath. *Photograph from a Pencil Sketch of Weston-Super-Mare, A.D. 1826.*

T. M. Barbour, 1, Brierley Street, Bury, Lancashire. *Photograph of the late Thomas Boothman.*

LENS APERTURES.—I would be very much obliged if, through the medium of this column of your valuable paper, of which I am a constant reader, you would inform me on the following point:—Some time ago I purchased a half-plate R.R. lens of ordinary focus, with plate diaphragms. There are four metal plates with the openings of 13-16in., 9-16in.,  $\frac{1}{8}$ in.,  $\frac{1}{16}$ in., but without marks of any kind to tell the apertures. Would you kindly tell me the average openings for a lens of this size, so that I may see what they stand for and get their *f* numbers engraved on them?—T. O. McNEILL.

You first require to know the focal length of your lens, which you can find with sufficient accuracy by focussing as sharply as you can at full aperture a distant object—e.g., a church spire. The distance from the focussing screen to the lens diaphragm will be (near enough) the focal length of the lens. To get the *f* numbers you must divide this number by the diameter of the various apertures. Thus, assuming the lens to be 8in. focal length, the *f* number of the 128 ÷ 13, or practically *f*/10.

RED-TONED BROMIDE.—In your issue of March 13 you gave us a formula for the red toning of sulphide-toned bromides. My employer was much struck by the tone produced; it was, in fact, equal to a red chalk carbon, and we did several large ones for the window. They were only there a few days when the colour began to go, and they seem to be going back, in a patchy manner, to their original sepia colour. Can you explain this? They were done strictly according to the instructions given. Have you yourselves had any experience as to permanency?—S. A.

A possible cause of the fading is stale sulphocyanide. We suggest increasing the proportion of gold to sulphocyanide, so that toning is complete in fifteen minutes at the outside.

FILMS.—I shall feel much obliged if you will kindly examine the enclosed films. I have developed them with pyro-soda developer, Ilford formulae. They took a long time for the image to appear, and I could not get density. I shall esteem it a favour if you will kindly let me know the reason of the failure to get good results.—SIDNEY E. BEGGS.

Your films are all under-exposed and also out of focus. They look as if you had been attempting impossibilities with rapidly moving objects in a bad light. A very short exposure with a lens of large aperture is necessary for such objects as these. You should also hold the camera more steadily.

PRESS PHOTOGRAPHY.—(a) If I take a photograph of public interest and send it to several of the weekly papers, if more than one accept it and pay the usual charge, can they get me into trouble for selling it to the others too? (b) Does the fact that I have sold the picture to one or more of the papers mean that the copyright

belongs in future to them, if they care to register it? (c) If it is not illegal to sell the photograph to several papers, is it considered an unprofessional thing to do, or is it the usual thing? (d) Does the fact that a subject has taken a prize in a competition prevent one using the photograph again for purposes of sale, exhibition, or other competitions?—PRESS.

(a) No, it is understood that you are offering it to others, unless you are being paid for the exclusive use. (b) Certainly not, unless you used your licence to use very loosely. See the article on "Copyright" on another page. (c) It is usual. (d) Not unless the sole copyright is transferred to the organisers as a condition of the competition.

**LENSES.**—(1) Can you give particulars of the cinematograph projection objective and wherein lies the difference in effect from an ordinary lens for camera work? (2) What is a positive lens? (3) Could you kindly inform me how to print P.O.P. by artificial light?—MOUR (Glasgow).

(1) A cinematograph lens is one of short focus, about 3 inches, and large aperture,  $f/3$  or  $f/2$ . Lenses of various types are made by most of the leading opticians specially for cinematograph work. (2) A lens which converges rays of light, that is to say, forms an image of an object.

**TRIPOD STAY.**—(1) Where I can obtain a tripod stay, which I remember seeing in the list years ago. It consisted, I think, of metal strips, to fasten inside the legs of a wooden tripod to prevent slipping. (2) Whether or not it is illegal for any person to copy names and addresses from marriage notices exhibited at a registry office, and whether a clerk in charge may prevent one from doing so (such copying for business purposes, of course)?—MARRIAGE.

(1) The tripod stays are supplied by Marion and Co., Soho Square, and, we imagine, by most similar houses. (2) We cannot say for certain, so you had better put the question to the Registrar-General, Somerset House. We should certainly say that the clerk is quite within his powers in refusing any one permission to make copies for business purposes, if he has reason to think it would cause inconvenience or annoyance to the parties concerned.

**LENS QUERY.**—(1) The extreme length of my studio is 21ft. I wish to take busts, full-length figures, and groups, say of 10 or 12. Allowing 3ft. at each end for camera and figures—6ft., leaves 15ft. between sitters and camera. Which kind of rapid portrait lens would be most suitable for my purpose? I have written several makers. One says that I cannot use a longer focus than 12in., another that I require one about 7in. Kindly give full particulars to guide me. (2) Would you say whether the mercury-vapour lamp is satisfactory for making groups, etc.? I have an idea that it would be easily damaged, which would be very awkward, as it might be difficult to have it repaired here. Please say what you think. Or would you consider the arc type of portrait lamp more satisfactory?—POLLY ANTHUS.

(1) The size of pictures you desire to take is not mentioned, but we will assume it to be the ordinary cabinet. With a lens of 9in. focus a distance of about 13ft. is required for a full-length figure, and one of such focus would do for groups, full-length, of several persons; but it would have to be one of great covering power, in proportion to its focus, such as those of the anastigmat type. If you require a rapid lens the stigmatic portrait would probably suit you, as its aperture is  $f/4$ . For large heads or busts we should advise you to have a longer focus lens. (2) The mercury-vapour lamp answers perfectly for portraiture. Of course, the tubes require handling with ordinary care, as they are glass, but of fair thickness. As good portraits are produced by one light as the other.

**RUSTY GRIFFO.**—We think the stain is exceptional for the developer you are using. It is difficult to remove any stain from the finger nails, but we would recommend you to try a few crystals of ammonium persulphate, rubbed on with a little water.

**FILTER.**—As a general rule, it is difficult to obtain the total of the separate actions of several dyes in one plate. This applies to bathing in a mixture of dyes or in three successive baths. The answer to your last question is, certainly not.

**J. W.**—The only way of remedying the negative is to send it to an expert retoucher for the obliterated figures to be knifed in. Of course, a mirror is the worst possible object to have in the

background when making a flashlight photograph, and the effect you have obtained would have been produced whatever the position of the camera, except perhaps one to the extreme right or left, a position, however, which would have been impossible in taking so large a group. Surely you could have covered the mirror with sheets of brown paper.

**J. A. C. (Bailieboro').**—We cannot undertake to carry out tests such as you mention. The reply given to our previous querist is correct, but if you obtain your supply from a photographic lab you may be certain of the photographic purity of the paper.

**S. E.**—You will not find any lens which will give you the depth you require with such a large aperture. The best suggestion we can make is that you use a lens of the longest focus possible, that is to say, as long a focus as the length of your studio will allow. This you can easily calculate by first finding the degree of reduction you require, and then working from the tables, pages 946, etc., of the "Almanac."

**DAMAGED BACKGROUND.**—I have a background which has been badly damaged by oil of some description (soaked through). Would you kindly inform me the best way to remove same in your next issue.—E. G. HARRIES.

You do not say the kind of background it is. If it is flatted we do not think that anything will remove the oil without at the same time disturbing the groundwork. You might, however, use benzol. If the background is in distemper, sponging with benzol will remove the oil without interfering with the distemper; but in any case we suspect some stain will be left.

**RESTORING POSITIVE.**—I should be greatly obliged if you would advise me if it is possible to restore the enclosed positive, and so the method of doing so. It appears to me that the image is still there but faded, and I am under the impression there is some method of intensifying same.—A. HUBBARD.

The positive is a Daguerreotype, and requires to be treated by the method we have frequently given in our columns. But unless you are accustomed to such work we would strongly caution you against attempting it, as the result will be probably disastrous to the original. You will see a note this week under "Analects on restoring Daguerreotypes."

**END OF REPAIRING LEASE.**—About two and a half years ago I bought the above business. My predecessor held a seven years' lease (which expires in June next), and it was transferred by the landlord to me. A few days ago the landlord called on me and inquired if I intended to renew the lease. I told him that I did not, as I had taken other and more suitable premises. He then told me that he should expect me to leave the place in good repair, as he could see it was not so at present, and it certainly not. Who is responsible for doing the repairs, seeing that I have only been in the place for two and a half years, and my predecessor occupied them for four and a half?—ANXIOUS.

Decidedly, you are responsible for the repairs, as you took over the lease, and, with it, all the responsibilities attached to it. Had the lease not been assigned over to you by the landlord the repairs would have fallen on the original lessee, and the landlord would have had no claim on you. The tail end of a repairing lease frequently entails a deal of trouble and expense.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Mr. C. Welborne Piper, as the result of experiments on the ferric-bromide bleacher, has found a means of removing from the former reducer its tendency to eat out faint detail. This result is obtained by the addition of bromide to the customary formula. (P. 319.)

Photographers' Premises.—Mr. Butt's article this week deals chiefly with matters of furnishing and decoration of the studio. (P. 320.)

Photographers' Fire Insurance.—Certain of the points to be borne in mind in taking out a fire policy on photographic premises are dealt with on p. 318.

Copyright Infringement.—The acts constituting infringement and the best steps to take in such events are the subjects of this week's "Copyright Conversation." (P. 322.)

Cinematograph portraiture is reported to have been revived by the Lamour company. The method is illustrated on p. 330.

Professor Pigeon, of whose so-called "Dixio" method (of producing stereoscopic photographs which may be of large size we give description) has suggested a new device for taking the pair of stereoscopic negatives in two large cameras, which nevertheless use their lenses at the proper stereoscopic separation. (P. 324.)

Mr. W. Thomas, writing on "Three Good Things," gives his experience of a new developer, finder, and type of printing paper. (P. 327.)

Mr. W. Michell contributes some useful notes on mounting pictures and precautions in making them. (P. 323.)

Captain Owen Wheeler, in a recent article, pronounces in favour of giving considerably less exposure in high-power telephotography than is indicated by calculating from the magnification. (P. 327.)

Exposure in Enlarging.—Commenting on Mr. Nixon's paper of last week we draw attention to the necessity of considering also even illumination of the screen. (P. 318.)

Three-colour screen-plates and developing tanks are among the novelties of the week. (P. 330.)

A further batch of correspondence on the portrait postcard appears on pp. 334 and 335.

A vivid side-light on cheap photography and the practice of portraiture by the semi-amateur is cast by an article in the "Daily Telegraph." (P. 326.)

## EX CATHEDRA.

### School Children and Cinematograph Entertainments.

The recent decision of the German school authorities with regard to school children attending cinematograph entertainments may serve as a timely warning to all those having interests in such performances. For a long time the authorities have been keeping a sharp eye on the cinematograph entertainments which are given in shops and halls in most of the towns and villages throughout the country. Complaints have been made that many of the pictures shown in these places are wholly unfit for children to see, and are likely to suggest evil to the young mind. We have ourselves seen pictures thrown on the screen in more than one German town, which, if not immoral, were certainly vulgar, and far from edifying, and as the greater part of the audience attending such entertainments were children, the action which the authorities have now been forced to take is very wise and necessary. While appreciating the educational value of a good cinematograph entertainment, the authorities at the same time warned those responsible for them that if any indecent pictures were shown they would have to take such steps as would prevent school children from attending these places. For a time there was some improvement, but gradually the proprietors lapsed into their old ways again, and now the order has been issued that school children are forbidden to enter places where cinematograph entertainments are given. Parents are asked to assist the authorities in carrying this out, and already cinematograph proprietors are complaining of the serious losses they are experiencing in consequence.

\* \* \*

### Filter Screens and Focus.

Dr. Lindsay Johnson, in "The Photographic Journal," discusses the variations produced in the position of the image by placing a filter screen in front of or behind the lens, and appears to come to the general conclusion that the differences are very small, owing to the fact that the colour screen is always, in practice, very thin, from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  mm. This is, however, by no means always the case. Some of the finest optically worked screens obtainable are about one-quarter of an inch thick, and such a screen may make a very appreciable alteration in focus. The Lumière screen is about  $3\frac{1}{2}$  mm. thick, thick enough, in fact, to compensate for the reversal of the Autochrome plate when the screen is used behind the lens, and it does this with very close accuracy, although Dr. Johnson states that, "as the thickness of a Lumière plate is usually from 1.8 mm. to 2 mm., placing the colour screen behind the lens will not compensate for the reversal of the plate in the carrier, as it will only neutralise a little over a third of its thickness."

Evidently here he is not allowing for the thickness of the screen. A plate 1.8 mm. thick requires a screen 3.6 mm. thick for correction (allowing an index of 1.5), and this is just the thickness of the Lumière screen we have in use. It is generally understood that the Lumière screen was especially designed to effect this correction and so to meet the convenience of photographers limited to fixed focus cameras. According to our own measurements it can be relied on to effect the necessary correction with a very close approximation to accuracy.

\* \* \*

**Exposure in Enlarging.** Last week we published an important paper, by Mr. John Nixon, in which he described a method of ascertaining the exposure for an enlargement without the trouble of making test exposures. Any such method would be of great practical value, but there are difficulties in the way that do not seem to have occurred to Mr. Nixon. He uses a special meter, and the factors that he employs to determine exposure are: the speed of the bromide paper, the aperture of the lens, the number of times of enlargement, and the density of the negative. By a piece of cleverly applied mathematics he shows that exposure with a lantern follows the same general rules as with a camera, provided the source of light is focussed by the condenser on to the projector, and that the image of the source thus produced is always larger than the projector. This fact appears to be new, but it is quite correct. There are, however, some matters that Mr. Nixon would seem to have overlooked, though they seriously affect the question. It is of the utmost importance to secure even illumination on the screen, and with incandescent gas the conditions for even illumination appear to be much the same as with small sources of light. That is to say, the image of the light formed by the condenser must fall, not on the projector, but some distance in front of it. We tested this many times, and have just repeated the tests so as to be able to give measurements. Using an incandescent gas lantern, with an eight-inch projector and  $5\frac{1}{2}$  inch condenser, to enlarge a quarter-plate to a little over whole-plate, we find that the illumination is impossibly bad when the image of the light is formed on the projector. The back of the projector is about 13 inches from the centre of the condenser, but the image of the light source must be 19 inches away to secure an even disc. In this case, therefore, Mr. Nixon's theory breaks down, for an essential feature of it is the situation of light and projector at conjugate distances from the condenser. Another essential feature is the complete filling of the projector with the light from the condenser. Assuming that an optical system can be found with which the first condition is fulfilled, then this second condition prohibits the use of a projector of very large aperture unless it is also of very great focal length. Suppose the lens to be two inches in diameter, then the condenser must enlarge the image of the mantle by two diameters at least to fill the projector, and if the scale of enlargement is at all considerable only a long focus lens will serve.

\* \* \*

**The Aperture in Enlarging.** It is well known by all practical workers that with small sources of light the stops have not the same effect as in the camera. Indeed, it is often found that the aperture can be very considerably reduced without producing any effect at all on the quantity of light passing through the lens. With a large source of light, such as an incandescent gas mantle, the conditions are somewhat different, but they are not necessarily parallel to those which prevail when the negative is illuminated by diffused light. When using a source of light smaller than the negative and a condenser to cause the light to converge towards the projector,

the concentration of the light within the projector is affected. The ordinary rules assume that the whole area of the stop is uniformly illuminated, and if there is any concentration of light in the centre, as is almost invariably the case with the lantern, the ordinary rules break down as regards the larger stops. With an arc light this concentration is very marked. With the incandescent mantle it is much less so, but in most cases it is probably enough to affect the action of the large stops. The factor of aperture is, therefore, one that it is difficult to apply correctly in the case of the lantern.

#### NOTES ON FIRE INSURANCE.

INSURANCE against fire is one of the business safeguards which, we believe, is taken by photographers in the great majority of cases, for the report of a fire at a studio is almost invariably accompanied by the remark that the loss was covered by an insurance policy. Nevertheless, even supposing that a policy be among a photographer's documents, it by no means follows that he has done all that is necessary for the insurance of his property against fire. For the wording of many policies may considerably reduce the amount which the photographer will recover in the event of a fire, and it will therefore be our object in a few words to draw attention to one or two points which should be noticed in taking out or renewing a fire policy. Moreover, certain acts, of which the photographer may know little or nothing, may easily invalidate a policy on which he is regularly paying the premium.

To take first one example of this latter aspect of the question. In many policies there is a restricting clause as to the use of pipe stoves on the premises to which the policy applies, and not infrequently the length of piping permissible is mentioned. Any extension of this length at a date subsequent to the taking out of the policy renders the latter void, unless the sanction of the company is obtained, and though the cause of a fire may have been in no way caused by the stove, the company are, nevertheless, in a legal position to repudiate claims for damages. Other instances could be quoted in which alterations to the premises have been made in a way to increase the risk of fire. In all these cases the policy should be handed to the agent of the company for endorsement.

Coming now to one or two other points in the taking out of a policy, we may premise our remarks with the statement of the late Lord St. Leonard many years ago, to the effect that "few policies against fire are so framed as to render them legally liable. Generally the property is inaccurately described with reference to the conditions under which you insure. They are framed by the company, who probably are not unwilling to have a legal defence against any claim, as they intend to pay what they deem a just claim without taking advantage of any technical objection, and make use of their defence only against what they may believe to be a fraud, although they may not be able to prove it." Modern experience may be fairly admitted to confirm the late Justice's opinion, for, as a rule, insurance companies deal fairly with fair and honest claims, and yet that is no reason why the photographer should not take the necessary precautions in having his policy drawn up.

In the event, say, of a photographer insuring the contents of his premises for £500, he should understand that, supposing the whole to be totally destroyed, he must first prove the value of the goods which were in the place at the time in order to recover that sum. Usually the total amount assured is divided into sections, say, so much on furniture, so much on fixtures and fittings, so much on apparatus, negatives, etc. Assuming that the insurance for £500 is divided somewhat as follows: furniture £150,

apparatus £150, fixtures £100, and negatives £100, we will propose for the purposes of explanation that, in the event of fire, furniture and fixtures only were damaged to the extent of £150, whereas apparatus and negatives were totally destroyed, say to the value of £200 in the case of apparatus and £150 in the case of negatives, these insured amounts being due to additions to the establishment subsequent to the taking out of the policy. It will be seen that though the damage sustained actually amounts to the full sum assured, yet recovery can only be made for £150 for furniture and fittings, £150 for apparatus, £100 for negatives, that is to say, for £100 less than amount insured for, although the total damage actually really amounted to the full sum. The companies will compensate only according to the limits of the different policies mentioned in the policy, and do not allow one to be set off against another. This, as we have said, is the legal position, although we have come across more than one instance in which the insurance company has departed from the strict letter of the policy, and, being convinced that the insured was a reasonable and honest one, has done as an act of grace what was not legally binding upon it. It should, however, be borne in mind that in the event of a policy being supplemented to a notably increased value necessary additions should be made to the policy. In all policies it is usual to place a limit on the value of certain items insured. For example, in the case of photographic apparatus a limit of £10 is frequently made the value of any individual lens, although many instruments may be worth three or four times that amount.

Some, it is true, may be of much less value than £10, but in the event of loss their small value cannot be averaged with that of the more costly ones, and only their actual value would be paid. The same thing applies to negatives, a limit to the value of which is also put on them individually, sometimes the value only of a shilling or even sixpence, although amongst them may be negatives of very considerable value to the owners. It must further be pointed out that even in the case of the destruction by fire of a number of insured negatives, the holder of the policy would not necessarily obtain from the insurance company the full maximum price of each negative. He would have to satisfy the company that they were of that value, which, of course, a very large proportion are not.

As we have already pointed out, these maximum values may be enlarged at an increased premium, but a better procedure is to take out a separate policy, say, for lenses of greater value than £10, in which the names of the makers of the instruments, their numbers, and their separate values are entered; then, in the case of their destruction, their full value can be recovered. The same course may be applied to valuable negatives, which can be insured to any value, although at an enhanced premium. Another point in regard to lenses should be understood, and that is that although old lenses may be of the greatest value to a firm, the insurance company, which usually takes pretty good steps to inform itself in such matters, will demur to paying even the full list price of the lens at the time of its issue. Many lenses of the old triplet or orthographic class are now worth a fourth or less of their original price.

## SULPHIDE TONING AND A NEW REDUCER.

In connection with sulphide toning it has been suggested recently that weak results may be due to a loss of silver in the fixing bath if the print contains any traces of hypo. This is impossible, as the following experiment shows. A negative partially treated with a hypo fixing bath, and then, after minute's washing under a strong stream of water, it was placed in a mixture of ferricyanide and bromide. In the case of a negative treated with hypo bleaching was very slow, and the final result was a much lighter deposit than in the rest of the plate. In developing the negative it was found that the hypo-treated portion of the plate was very considerably reduced in density, and it was clear that some silver had been lost in the bleaching process. A paper print will, of course, hold a considerable quantity of hypo, and as it is not very easily removed, there is a certain element of risk with prints. It is, therefore, obviously advisable to wash very thoroughly and carefully before applying the sulphide toning process. Unfortunately, the popular ferricyanide and bromide bleaching bath has not the same action on hypo as the bichromate and hydrochloric acid, or the ferri-bleacher. Both these are powerful hypo eliminators, and will speedily destroy any hypo contained in the film, whereas the ferricyanide-bromide bath has no such effect. The latter is, however, undoubtedly the best bleacher of the three, and is one that is generally most serviceable. It is not impossible that many of the troubles met with in sulphide toning are due to the use of imperfectly washed prints that contain hypo.

### A New Reducer.

The fact that silver disappeared when the ferricyanide-bromide bath was used in the presence of hypo, naturally suggested that

it might be worth while trying the effect of the ferricyanide-bromide mixture as a substitute for the simple ferricyanide in Farmer's reducer. Ferricyanide alone attacks silver very slowly, and it occurred to me that this fact might possibly have something to do with the effect that "Farmer" has upon contrast. A mixture of ferricyanide and bromide acts far more rapidly, hence it appeared likely that it, when used in the reducer, would affect contrast in a different fashion. A first trial was so promising that I made a number of tests on various negatives, with the most satisfactory results. Equal parts of ten per cent. solutions of potassium ferricyanide and potassium bromide were mixed, and a few drops of this solution were added to two ounces of ten per cent. hypo. This reducer acted very regularly and steadily, and showed no specially selective action on the shadows, as is the case with the ordinary formula. It reduced the high lights, and brought out all their details without eating away the shadows, though the latter, of course, could be destroyed by applying the solution long enough, just as they could with any other reducer.

Without photometric tests it is impossible to say whether this new reducer has the same effect as persulphate, but it certainly has a very different effect from the ordinary Farmer's formula, and is also more reliable than the persulphate, which at times is very erratic in its behaviour. The first tests were made on waste negatives of no value, but when I found the solution acted so well I had no hesitation in applying it to more valuable negatives that were rather too hard owing to over-development, and in every case the effect was all that could be desired.

C. WELBORNE PIPEE.

**WARNING.**—Photographers in North Surrey and elsewhere who have been visited by a Frenchman of German appearance are warned to guard to him by one of our correspondents, from whom, on

charity being shown him, he absconded, taking with him a half-plate camera fitted with Beck lens, with six double dark slides, the whole packed in grey waterproof case.

## THE MODERN NOTE IN THE DESIGN AND FITTING OF PHOTOGRAPHIC PREMISES.

### V.

[Under this title we continue, with the following article, a series of chapters by Mr. Drinkwater Butt, F.R.P.S., on the principles which should guide the photographer in the external design and decoration of his place of business, and in the arrangement and appropriate equipment of its various apartments. Photography being essentially an "artistic" business, taste and style need to be more in evidence than is necessary in businesses which are frankly and wholly commercial in their character. Therefore, while it is not possible to prescribe any plan which can be followed in particular cases, general rules can be laid down in such a way that a photographer can take advantage of them in giving his establishment, both outside and in, an air of distinction, which is bound to carry weight with his townspeople, and must turn out to his commercial advancement. Of course, a fortune may easily be squandered on such adornment of the studio, but in these articles Mr. Butt will confine himself to such schemes as a photographer in a moderate way of business need not consider beyond his means. Moreover, the articles will be of assistance in pointing out how particular materials may be used, even on the smallest scale, in adapting or improving existing premises. The notes will conveniently be divided into four sections:—

Shop-front and Show-case.

The Reception-Room.

The Studio.

Planning complete Premises.

The last chapter will consist of a description of as complete a set of photographic premises as can be imagined—an establishment, in fact, which but few living photographers would feel justified in putting up. Yet the scheme in its various parts can be commended to the study of even the small photographer, on account of its detailing arrangements, which can be abstracted in pieces from their surroundings and utilised with advantage in businesses which are anything but magnificent in size.—Eps. "B. J."]

WE now proceed to deal with the fitting and furnishing of the studio, an apartment in many respects the most important in premises devoted to photography, and certainly the one which receives most attention, and criticism or appreciation, as the case may be, from the clients of the establishment. This being so, it is very surprising to find that in a very large number of cases it appears to be the place upon which least attention to appearances is bestowed, even by some very good photographers. In studio after studio that one goes into, one finds dirt, dust, and confusion; heterogeneous collections of more or less dilapidated apparatus, mingling with furniture which is old without being antique, and all the débris of a workroom mixing very often with some sort of apology for the proper appointments of a dressing-room. Shabby backgrounds, which even in their palmiest days were miracles of impossible perspective and preposterous decoration, hang on crazy frames behind "rustic" gates and stiles, and alongside "property" boats and ship's masts which no sailor would recognise; while in the midst of a litter of retouching-desks, printing-frames, etc., we find *papier maché* rocks unknown to any geologist, and pedestals, columns, and vases of forms quite undreamt of by the architect, filling up the space which is required for the proper posing of the sitter and the manipulation of the camera.

Into such places it is no wonder that daintily dressed ladies go but once, and send their children and friends not at all; or that no sitter feels at his or her ease, or, as a natural consequence, looks unconstrained or at home in the resulting picture. And yet I have known photographers possessing studios of this kind wonder at the lack of sitters and the slackness of business! As a remedy for this state of things, the first point to be insisted upon is the necessity of abolishing from the studio all kinds of working apparatus save that actually needed for the purposes of portrait-taking, to which the room should be wholly and solely devoted. Printing, retouching, and similar work not only cause dirt and litter, and take up valuable space, but also introduce into the studio the presence of assistants, who distract the attention of the sitter, and often cause the nervousness and self-consciousness which are so inimical to good photographic portraiture. It is a good rule to have no spectators—not even the sitters' friends, when they can be conveniently excluded—in the studio, and much better results are then generally obtained. The next

thing is to see that the actual working apparatus of cameras, reflectors, blinds, backgrounds, etc., is in perfect order and ready for immediate use, so that no defects may interfere with the swift, smooth completion of his arrangements which characterises the good operator.

As regards backgrounds, these are generally too many in number and too poor in quality, and so little conducive to good work though taking up a lot of room. For even a very large business some ten backgrounds at a time should be amply sufficient—such, say, as a light and a dark landscape, a light and dark interior, a couple of cloud effects, vertical and horizontal gradations, and flat light and dark tints of the well-known Empire cloth. A round dozen may be made up if the wall at one end of the studio is covered with a good bit of wood panelling (obtainable at a moderate price from Messrs. Houghtons Limited), and at the other with Lincrusta, Lynecastle, or some other of the relief decoration materials.

### A Suggested Complete Studio.

In the drawing of a studio to be given next week, there is shown at the east end a semi-circular recess, the wall of which would be treated with plain distemper or covered with a plain canvas, and this forms, with the ordinary lighting, a natural gradated background, the effect of which can be modified or altered by raising either or both of the halves of its canvas-covered framed ceiling, which are hinged at the centre, and when opened admit top-light from a skylight above, as will be seen from the plans to appear in a later issue of the "B.J." The front opening of this recess is 8 ft. square, or the size of an ordinary background, and behind the frieze above it would be fixed one or two rollers to carry examples which could be lowered in the ordinary way when required. The other painted grounds would be best mounted on one of the patent portable roller background stands, which can be readily moved into any position desired. One of these is shown in one of the photographs of a "North Country Studio" which forms one of our later illustrations. When any background becomes at all shabby or hackneyed by constant use it should be disposed of, and something fresh obtained in its place, so that the photographer's work may not become monotonous and stereotyped, as it often tends to do when the same backgrounds and accessories are used over and over again.

### Studio Backgrounds.

A great quality to be sought for in the selection and use of backgrounds is simplicity, with as little distracting as possible; and that little, correct as regards form and perspective, it being always to be remembered by the photographer, though it appears to be generally forgotten by the background painter, that it is only a subordinate, and not principal, part of the picture in which it is to appear. I have even known a photographer lament the necessity of placing a picture in front of the elegant background which was really "a picture in itself." I am quite aware that it is very difficult to find painted backgrounds of the simple and broad character which I am advocating, and that it is still more difficult to get them done to order; but still, by constant diligent search through the dealers' specimen books they sometimes to be discovered, and when found should be snapped up, as the chance may not soon occur again. A very decent specimen, obtained in that way, appears in its accompanying foreground in one of the photographs of "North Country Studio" just referred to.

### Have Accessories "Correct."

Which the same principles hold good with regard to accessories, especially those of an architectural nature. Occasionally comes across a decent pedestal or balustrade, but when the maker of accessories soars to columns, piers, and even wrought-iron gates, then his productions become fearful and dreadful indeed. Fortunately, these things are not very often needed for ordinary sitters in modern dress, but any examples which the photographer may find it convenient to have for personal use should at least be chosen for their correctness of form and style, and when not in use may be very conveniently kept in some adjacent store, and not allowed to lumber the studio more than can be helped.

### "Homelikeness" the Aim in Studio Furnishing.

The most general and useful accessories are, however, those which take the form of articles of furniture, and with regard to these it may be at once said that the objects to be most desired are usually those made especially for photographic purposes, not only because they are to be found in so many studios, but also because they are generally heavy, ugly, and quite unlike any furniture which clients would probably have in their own homes, and so feel (and look) most at home amongst. Chief amongst this class of article is the so-called "posing chair," which takes to pieces and fits together again in all sorts of odd and wonderful ways, something like that piece of furniture which, according to the poet, "contrived a double debt by, a bed by night, a chest of drawers by day." In none of its permutations, however, does this article look like any piece of furniture, nor does it feel comfortable to the sitter, or, as far as I can see, facilitate the work of the photographer in posing him. For vignettes a narrow-backed chair revolving on a stand is certainly a convenience, as on it a client can be easily turned a little as the exigencies of lighting and point of view requires, but, apart from this, none of the "bags of tricks" so much affected by some not very successful photographers, who trust rather to mechanical contrivances than their own skill, are worth bothering with. What is wanted in a studio is simply a good variety of furniture which a photographer's clients are likely to have in their own houses, amongst which they will look most at home, and which can always be treated so as not to become obtrusive in the picture or detract from its artistic effect. Longfellow's dictum, "That is best which is nearest; shape from that thy work of art," applies here in other cases. Most of the articles should be those found in ordinary dining and drawing-rooms, or even more preferably,

in the "parlours" of our not too immediate ancestors. The modern revival of interest in furniture and decoration has fortunately swept from our houses the horrors of the "Early Victorian" period, the mahogany and horsehair, the white-and-gold wallpapers, the veneer and sprawly, coarse carving, the beads and Berlin wool work; and it is well that our studios should reflect the better taste now to be found in our houses. Of course, in furnishing a studio no uniformity of style can or should be attempted, as it is necessary to have a good variety of accessories to suit the various classes, ages, sexes, and costumes of sitters; but each piece should be true to its own style and artistic in form, and all should lean rather toward simplicity and severity than to elaboration and gorgeousness if they are to take their proper places as subordinate objects in pictorial schemes of composition, and not assert themselves at the expense of the real subject of the picture. I have known some photographers either very proud of their elaborate furniture, or incapable of posing a human figure by itself, so overload their portraits with accessories of all kinds that the photographs really ought to have been inscribed with the legend, "Puzzle: Find the Sitter!"

Nearly all the so-called antique styles of furniture are useful in a studio, it having been reserved for the mid-nineteenth century to combine both ugliness and bad workmanship; but, of course, nowadays really good examples of the earlier styles are becoming every day higher in price and more difficult to obtain. In default, however, of original pieces by Chippendale, Sheraton, or Hepplewhite, or of the Georgian, Queen Anne, Jacobean, or Tudor periods, there are now exceedingly good reproductions to be obtained correct in form and almost, if not quite, equal in workmanship to the originals themselves, from such firms as Waring and Gillow, Heal and Co., or Liberty's, of Regent Street.

As regards chairs and tables, those mentioned in our last article on the reception room would also be of service as accessories in the studio, the furniture for which should be almost all chosen for its lightness of effect and generally artistic lines, which are the qualities required in place of the heaviness and ugliness of the fittings of so many of the operating rooms of the past.

### Genuine Secondhand Old Furniture in the Studio.

In the large design for a studio interior, the furniture shown is partly modern and partly antique, as also in the photographs of the "North Country Studio," in one of which latter the black seventeenth-century armchair is a specimen of the bargains which may even yet (though with far less frequency than of old) be still obtained by the diligent seeker after the artistic and the antique, it having been picked up at a farmhouse sale for the magnificent sum of half-a-crown. The frame of the mirror hanging over it in the photograph cost only sixpence more at a secondhand shop, while the old earthenware tankard of grey and blue which appears, though somewhat indistinctly, in the centre of the corner cupboard over the staircase in the same picture cost nothing at all, the miscellaneous auction "lot" of glass and china of which it formed part having been at once resold, minus the tankard, for the price originally given for the whole!

### Comfort and Taste in Studio Decoration.

To pass on, however, to the fixed decorations of the studio, it may be laid down that the general scheme, in most cases, should be a light and airy one, not only that the apartment may, by its brightness and cheerfulness, have a good effect upon the spirits and consequently also upon the expressions of the sitters, but also that all the light possible may be obtained when wanted for large groups or other work requiring plenty of illumination. Superabundant light, whether direct or reflected, can be easily shut out or cut off by blinds or screens, while a naturally dark or gloomy interior cannot be lighted at will.

Therefore, speaking generally, ivory or creamy white may be recommended for ceilings and woodwork, and warm soft greys for the walls, any coloured decoration being sparing in quantity and worked out principally in dull pale yellows, buffs, and blues. This scheme was followed in the "North Country Studio," the ceiling being creamy white, the woodwork of the same tint slightly picked out with ochre, the walls covered with an ingrain paper of a warm grey, with a frieze of the same having a simple design in pale ochre, dull blue, and light red. The floor was covered with a plain warm grey cork carpet, with mosaic pattern border, on which the studio camera, background stands, etc.,

moved easily and noiselessly. In a more picturesque studio, a cork carpet might have been replaced by a parquet floor, or the effect of the latter have been obtained in an inlaid linoleum, which is also a capital material for the covering of studio floors, especially in busy establishments where there is much traffic. Large carpets are not generally satisfactory, as they are difficult to keep clean, uneven in wear, and more often than not unpleasantly obtrusive in pattern, to the great detriment of the full-length pictures or groups in which the carpet is included.

DRINKWATER BUTT, F.R.P.

(To be continued.)

## CONVERSATIONS ON COPYRIGHT.

[COPYRIGHT.—The sole and exclusive right of copying, engraving, reproducing, and multiplying any photograph of the negative thereof by any means and of any size. [Extract from the Copyright (Works of Art) Act (1862).] The present (fourth) chapter of this series of notes deals with perhaps the most important part of copyright law, viz., the ways in which a photographer's copyright may be infringed, the ways in which a photographer is liable to infringe the copyright of others, and the rights and penalties which apply in these circumstances. Those who desire to acquaint themselves completely as to copyright dealing (I.) with ownership of copyright, (II.) with registration of copyright, and (III.) with sale and part sale of copyright.

### IV.—INFRINGEMENT OF COPYRIGHT.

Q.: By "infringement" is meant, I presume, the unlawful use of a copyright photograph—that is to say, making copies and enlargements?

A.: The Act distinguishes between two classes of infringer. The first and most common are those who commit, or cause to be committed, the unlawful copying of a photograph in which there is copyright. The second are those who import reproductions of a copyright photograph, which they know to be unlawful, into the United Kingdom.

Q.: In the second case the infringer appears to be held responsible only when he is aware of the unlawful nature of the goods he is selling. But what about the newspaper (or photographer) who copies a photograph not knowing, and not able to find out, whether there is copyright in it?

A.: That is so. The importer is held guilty of infringement only when he is proved to have acted with knowledge of the nature of the goods. But in all other cases, viz., those in which acts of infringement are done, or caused to be done, ignorance is no excuse for infringement.

Q.: What are the acts which constitute infringement?

A.: The Act says that no person, "not being the proprietor for the time being, shall repeat, copy, colourably imitate, or otherwise multiply for sale, hire, exhibition or distribution, or cause or procure to be repeated, copied, colourably imitated, or otherwise multiplied for sale, hire, exhibition, or distribution."

Q.: Repeat or cause to be repeated? Then this means that in the case of my making an enlargement of a photograph I am just as liable for any infringement as the person giving me the order.

A.: You are. In a case of infringement in such circumstances both you and your customer might be proceeded against by the owner of the copyright.

Q.: Equally, in the event of an infringement of a copyright of mine by, say, the issue of a poster, both the firm which ordered the poster and the actual producer are liable to action for infringement?

A.: Certainly; this clause in the Act is a two-edged sword which cuts both ways.

Q.: In quoting just now from the Act, you describe a "colourable imitation" as an infringement. What is a "colourable imitation" of a photograph?

A.: The term should almost explain itself. It means a copy

which is not exact: which differs from the original in certain particulars. Fortunately it is that the clause occurs in the Act, otherwise it would be difficult for a photographer to obtain redress in the event of his photograph being redrawn with slight alterations by artists.

Q.: I take it, then, that a copy is none the less an infringement even if it differs from the original in size or other respects?

A.: Certainly; that is so. An enlargement, a lantern-slide by reduction, a three-colour reproduction, and a wash-draw or engraving, are all equally infringements of a photograph made without the permission of the owner of the copyright.

Q.: Of course, a copy in one process (or colour), say, carbon, is an infringement of a photograph in another, e.g., platinum.

A.: Most certainly. So long as a copy can be proved to be a copy of all or part of the photograph it (the copy) is an infringement.

Q.: The Act, I see, defines other things besides sale in connection with the disposal of copies.

A.: Certainly. It is not necessary to sell copies in order to constitute them infringement. The Act says "for sale, hire, exhibition, or distribution." "Exhibition" clearly includes the case of a photographer who makes (or causes to be made) an enlargement from a negative he has taken for a customer and been paid for in the usual course. As we learn from "Conversation I," the copyright is the customer's, and the photographer has no right to make a copy to be displayed or exhibited (not even in his own shop) without the customer's consent.

Q.: On the other hand, I take it that in the case of a person to whom a sitting has been given, he is guilty of infringement if he gets made an enlargement of the photograph. For example, I recently obtained a sitting from a well-known actress who was performing in my town with an amateur company. I registered the copyright, and every copy was stamped "Copyright." Now an enlargement of the same photograph has been presented to the lady by a member of the company. An infringement of my copyright, is it not? But as I do not know who made the enlargement, I would like to ask if the person who ordered it to be made is equally liable.

A.: Certainly; the person who gave the order is covered by the wording of the Act—"cause or procure to be repeated."

Q.: Another case of a third party I would like to mention. A person (A) purchases a print of mine and sends it to

newspaper, where it is reproduced under his name. Is the infringement the work of the newspaper people or the person who offered the photograph to them?

A.: The person A cannot be said to have caused the reproduction of the photograph in the newspaper. This is the work of the editor or proprietors, and they alone are liable in this instance.

Q.: The person (A) in the case I have just mentioned excused himself by saying that he thought he was entitled to allow a print which he had purchased to be reproduced.

A.: Of course, that is ridiculous. Buying a print has nothing to do with acquiring the right to copy it, unless there is some reason to think it is a photograph in which there is no copyright.

Q.: I suppose it is fair to assume that there are photographs which can be copied with impunity?

A.: It is safer and nearer the truth to assume that there are none. Even if a photograph is not registered, it becomes an offence to sell copies once the copyright has been registered, and therefore it is foolish to trust to the owner of the copyright for finding out.

Q.: What is the best course to take when a photograph of mine has been copied, say, by a newspaper or postcard publisher?

A.: You must first convince yourself that you are the owner of the copyright. This is the case (1) if you took the photograph on your own account without payment, or (2) if the copyright was reserved to you in writing at the time the photograph was taken, or (3) if the copyright was assigned to you by agreement. Also, in order that you should be in a position to take action in respect of the photograph, you should have it registered before the infringement.

Q.: Suppose the copyright is mine, but that I have not registered?

A.: Legally, you have sustained no wrong by the infringement; but if you register at once, you then obtain certain legal powers which may still be considerable. You cannot claim penalties, but you can claim damages, but only those sustained subsequent to the registration.

Q.: One is as good as the other, isn't it?

A.: No. To obtain penalties you have only to prove the infringement; to get damages you have also to prove the damage—very often not an easy matter.

Q.: At any rate, you advise me to register the photograph at once, and then?

A.: You should then write to the infringing parties a letter in which you show that you assume the infringement took place through carelessness or ignorance of your rights—not from a desire to steal something from you. In other words, write a courteous note asking for the adjustment of the matter.

Q.: Should I name an amount for which I would be prepared to settle the matter?

A.: Unless you have fully decided not to take any legal action, you should on no account name any sum, because the demand might prevent your securing damages, and if you were afterwards claiming damages the sum you had named might be held to be the amount at which you estimated the damages.

Q.: But if I was decided on either settling without legal action or letting the matter drop could I not offer to take a sum in settlement?

A.: Some photographers have done well by making it a rule to accept double the usual fee for photographs used without their permission.

Q.: As a matter of fact do I not read in the Act that the penalty for each offence is a sum of money not exceeding £10?

A.: That is so.

Q.: Well, if a newspaper with a large circulation is made to give me the smallest sum for each infringement, viz., one farthing, the total would be a large amount out of its pocket.

A.: You are wrong in assuming that a coin of the realm must be paid as penalty for each infringing copy. Formerly the judgments were on that basis, but since 1901 it has been held that the court may award a lump sum, which, if divided by the number of offences, will give for each offence a fractional sum of money smaller than any coin of the realm.

Q.: There is one last point I would ask your opinion on. How do I stand as regards another photographer who copies my local views by placing his camera in the same position as those originated by me?

A.: Hard as it may appear, you have no remedy whatever. He is not copying your photographs, though virtually he might just as well—the injury to you would not be less. But clause 2 of the Copyright Act is very clear on this point. It upholds “the right of any person to copy or use any work in which there shall be no copyright, and to represent any scene or object, notwithstanding that there may be copyright in some representation of such scene and object.” This applies to particular selections of a landscape, as well as to paintings such as of old masters, the copyright in which has expired.

## NOTES ON MOUNTANTS.

### The Starch-Paste Mountant.

It may seem a little late in the day to say anything about the methods of mounting photographs of the various kinds at present in vogue; yet, judging from the questions that are frequently replied to in the “Answers to Correspondents” columns, it occurs to me that a few notes may not be altogether out of place, while they may be useful to some, especially to recent recruits in the ranks of our art-science. The chief considerations in the selection of a mountant are that it must have no deteriorious action on the picture, that it should be convenient to use, and at the same time thoroughly adhesive. So far as silver prints are concerned, this matter is of serious importance. It is so much so, however, with carbon or other pigment pictures; for with them almost any mounting medium may be employed with impunity. A mountant that might cause a rapid deterioration of a silver print would be quite inert were it used for a carbon print. The same might be said, though perhaps in a less degree, with reference to platinum prints.

Undoubtedly the most generally employed mountant at the present time is starch paste, and as an all-round adhesive for photographic purposes it is hard to beat. Yet it has its inconveniences, like all other cements, though they are but trivial. One is that the paste will not keep. Starch paste when made does not keep more than a day or two, as it has a tendency to become watery, and then loses its adhesive properties; furthermore, if used stale, it is liable to act injuriously on silver prints, particularly if they are on thin paper. Starch paste should be made with the best white starch, and be used the day it is made, then it is in its best condition in every way. If pictures on thick paper, in the dry state, are mounted with starch there is, in inexperienced hands, sometimes a difficulty in getting them to stick firmly at the edges. This difficulty can be got over by making the paste thicker and rubbing it well into the paper, particularly at the edges. If the prints are

mounted wet there is sometimes a distortion produced through the mouter straining the paper in getting it into position on the mount. One sometimes sees prints that look very much as if they had been badly trimmed; this is often not due to bad trimming, but to the paper being stretched in the mounting. Another trouble with starch as a mountant is that if the print is put upon thin cardboard, or thick paper, the margins where dry are cockled. This trouble, however, is inherent, more or less, to all adhesives of an aqueous nature. When large pictures on thick paper have to be mounted the best way is to make the starch thicker than usual, and rub it on with a good size piece of sponge, distributing it evenly all over. The print should then be allowed to rest for a minute or so to allow the paper to expand to its fullest. If, then, the surface shows that any portion appears to have become partially dry by absorption the whole should then be lightly gone over again with the sponge before it is laid on the mount. In this way creases, due to the unequal expansion of the paper, are completely avoided.

#### Gum as a Mountant.

Gum and dextrine are very convenient adhesives, but the latter can at once be put out of consideration from the fact that the commercial varieties are almost invariably acid, and therefore would be likely to have deleterious effect on the prints. Gum, on the other hand, is good, though of late years it has not been held in good repute, probably because it used often to be employed after it had become decomposed, sour, or mouldy. Some little time back an editorial note referred to this subject, and mentioned some silver prints that were mounted with gum fifty years ago, and were in a perfect state. I myself have seen some nearly as old, and they show no signs of fading. If gum be used, however, it should be good Senegal or Turkey gum, and be freshly dissolved, unless when it is dissolved a small quantity of some antiseptic is added, such as a drop or two of carbolic acid or oil of cloves. Then it will keep good for many weeks, and be ready for use at any time. What is sold as "office gum" should be studiously avoided, as one never knows of what it consists; sometimes gum is conspicuous by its absence. I have heard that even bicloride of mercury figures in some of these office gums as a preservative. If such a cement were used for mounting silver photographs, most of us know what would be the ultimate end of the pictures.

#### Gelatine Mounting Mixtures.

Gelatine is a most excellent mountant for photographs of all kinds, and it is less likely to cockle mounts on thin card than

either starch or gum. But the right kind should be selected or it may be found inconvenient in use. What is required for the purpose is a pure gelatine of poor quality—as a gelatine. This description may seem a little paradoxical to some. By low quality is meant one that does not yield so stiff a jelly with a given quantity of water and does not jellyify or set so low a temperature as do the higher grades, such, for example, those of the character employed for emulsion purposes—Nelson's "X opaque," and others. It is from the use of the latter kind that many have not been able to get on satisfactorily with gelatine as a mounting medium, although they imagined they were using the best for the purpose simply because it was the most expensive. The best I know of for our present purpose is either Cox's "soap" gelatine or Nelson's "No. 2 soluble." These are both pure—that is, free from acid and other impurities—inexpensive, very adhesive, and set very slowly. If those of the highest grade just alluded to were employed there would be the difficulty that the solution would become "jellied" before a large surface could be coated, and then there would be little or no adhesion. Many of the fine-looking, colourless foreign gelatines are acid, and, therefore, apart from their quick setting properties, they are unfit for mounting silver prints with. With suitable gelatines, such as we are speaking of, a considerable proportion of alcohol may be introduced into the solution in place of water. With this addition the mountant, when used for prints on thin mounts, causes cockling of the margins scarcely at all. In the "Almanac," page 834, a formula is given for such a mountant. In place of the gelatine mentioned I prefer the Nelson's "No. 2 soluble" or Cox's "soap." With either of these the proportion of water may be decreased and that of the spirit increased beyond those given, so that the risk of cockling is still further reduced. If the formula were followed with a high-grade gelatine the latter would in great part be precipitated on the addition of the spirit. The solution with the alcohol keeps well by reason of the antiseptic properties of the spirit, and it only requires the vessel containing it to be placed in warm water, when it is at once ready for use.

Even such desultory notes of the above cannot be penned without a reference to dry-mounting, that most perfect method of attaching the print to its support. For safety and certainty the process admittedly outdistances other mounting methods, and its adoption inevitably follows the desire to present the finished photograph to the very best advantage. The appliances and materials now procurable for the process may be said to have brought the method within the reach of all.

WM. MICHELL.

## STEREOSCOPIC PHOTOGRAPHY BY THE DIXIO METHOD.

The ingenious system of stereoscopy by which large prints—up to, say, 7in. by 5in.—may be used has been already mentioned in our pages. M. Pigeon, of Dijon, the inventor, now sends us a description of the methods employed in making the negatives and prints for the Dixio stereographs, some extracts from which will be of interest, as the processes employed may be adopted with or without the inventor's specially designed apparatus.

The Dixio system, it should be explained, requires that one of the prints should be reversed as regards right and left, and in order to obtain a pair of negatives—one of which is so reversed—a special camera is made to M. Pigeon's design by M. Gilles, of Paris. This, shown in Fig. 1, consists of a twin-lens instrument, one-half of which is fitted as a reflector camera, the mirror serving not as in an ordinary reflex camera merely for the focussing of the subject, but for the actual taking of the negative on the plate. This special instrument is, however, as we have said, unnecessary for the working of the Dixio system, inasmuch as reversal of the print may be introduced at several subsequent stages.

In the first place, the pair of negatives may be taken upon roll or cut film and one of them printed from the reverse side of the film.

Fig. 1.

Or, again, the print from one of a pair of glass negatives may be taken in single transfer carbon and a reversed print thus obtained.

however, it is desired to prepare two prints by the same process by glass negatives, one or other of the negatives can be removed from its support and laid down again, with the reverse in contact with the new support. For this purpose M. Pigeon suggests to employ a process, in which the dry negative is placed in solution of

Water .....	100 parts
Commercial formaline .....	15 parts
Soda carbonate .....	5 parts

which it is allowed to remain for about ten minutes. It is covered over with a tuft of cotton wool on removal from this bath allowed to dry, without artificial warmth, which it does in from

Fig. 2.

twenty-four to forty-eight hours. When dry a penknife is used to cut the gelatine through to the glass at a distance of about 1-16 in. from the edges of the plate, and the gelatine film can then be removed. It can be printed from either side, and is kept between glass plates under a slight pressure, or it may be cemented to a glass support by means of a 5 per cent. solution of gelatine. As far as we have spoken of contact printing, but it is obvious that simply reversing one of the negatives in the enlarging carrier as used in contact printing may be made as readily as one produced in the ordinary way.

In trimming the prints some little care is necessary. One print is held flat and some prominent object near to the right-hand side is used. By means of a pair of compasses or a strip of paper the

Fig. 3.

distance of this point vertically above the lower edge of the print is measured. Then the same distance of the same object in the second print is marked off on the latter. A similar series of operations being done in the case of a second prominent object in the print, the lower side of print No. 2 is trimmed along a line formed by joining the two points thus obtained. The print is then ready for examination in the special pattern of Dixio stereoscope, for a description of which we would refer our readers to the "Almanac," p. 609, Fig. 27.

advising the use of a camera of the 13cm. by 18cm. size, which is actually the American 7 by 5, but a little larger than the English

half-plate, M. Pigeon suggests the following method of making a pair of negatives suitable for the Dixio stereoscope.

Two lenses are provided of the same focal length, say of 6 in., and are mounted on the front panel of the camera, which is provided with the usual stereoscopic division. A plate bearing two negatives is thus obtained, one of which—that made by the left-hand lens—it is usual to reverse.

In making use of two separate cameras placed side by side on the same support, and provided with lenses of the same focal length, the worker has the advantage of being able to adopt any desired separation of his lenses, and so adjust the degree of separation to that necessary for dealing with objects different distances from the camera (Fig. 3).

Another advantage of the two separate cameras is that both can be laid on their sides and a stereoscopic print thus obtained at a greater separation, but of the landscape form, a latitude which is not permitted by a single camera, in which both pictures must necessarily be of the upright shape.

M. Pigeon suggests a very ingenious device for making large stereoscopic prints with two cameras while still preserving the proper stereoscopic separation of the lenses. He places both cameras on a board, as shown in Fig. 3, but with the axes of the two lenses—the focal length of which is, of course, the same in each case—at right angles. A mirror is placed in front of one of the lenses at an angle of 45 deg. to the axis, and the arrangement,

Fig. 4.

as shown in Fig. 4, causes the camera B to act as though it actually were in the position of B<sup>1</sup>.

The advantage of this method is that large prints may be taken with the proper stereoscopic separation.

This plan has the advantage that one of the negatives is obtained reversed, and, as for the mirror, a piece of good mirror glass has been found to give satisfactory results.

M. Pigeon suggests that a convenient way of entering upon his system is for two friends to use their cameras together, each, of course, having a lens of the same focal length. Both could make use of the pair of negatives thus obtained, and the prints would thus be obtained at a reduced expenditure.

M. Pigeon also points out that a single camera, which is given quite a slight displacement, may be used for producing the pair of negatives.

It will thus be seen that the salient feature of the Dixio system are, first, the facility of preparing each print either with one or two cameras, and in such a way that the subject may be taken either in the so-called portrait or landscape way of the plate. Moreover, as M. Pigeon points out, the form taken by the stereoscopic prints gives greater facilities in using photo-mechanical reproductions of such prints in a form in which they can be handled by the publishing trade conveniently. It is not too much to hope that a proper appreciation of these facts will lead to a revival of the stereoscope among the general public.

## EAST-END PHOTOGRAPHY.

(An Impression of Cheapest Photography, from the "Daily Telegraph.")

"LADY, lady, you dunno wot you look like till you've 'ad your photo taken." Touchy people might think that a doubtful compliment. Cautious people would hardly reckon it an inducement to face the camera. But the bland and bearded gentleman with the handbills knew his public. Two gorgeously-attired maidens—Solomon in all his glory was certainly not arrayed like one of these—lingered to listen to the voice of the tempter, and turned to the glass doors which bore the mysterious legend "Weather no object." Within, "twelve beautiful portraits" of their fair faces could be obtained for 3d. As a guarantee of good faith, the window displayed what at a little distance looked like a large draughtsboard, but on nearer examination resolved itself into a kind of crazy quilt composed of the physiognomies, reduced to postage-stamp size, of the fair women and brave men of the locality. Few of us, perhaps, would look our best on a postage stamp. A national portrait-gallery on that scale would turn the most amiable of men into a misanthropist. The process of reduction to the farthing size is one which few of us are designed to face with dignity. But there was no reason why anyone with money in her purse—and the two gorgeous maidens were certainly carrying a good deal on their backs—should limit her ambitions to the farthing order of art. Six of the carte de visite size might be had for sixpence and six cabinets for a shilling. At this rate one might rely on being adorned by the whole dignity of human nature and something more if necessary. The triumphs which decorated the window showed an array of gentlemen, diverse, indeed, of feature, but all alike of an unspeakable majesty of demeanour and amplitude of coat. They were not happy. Uneasy lies the head that fronts a lens. But they were aware of the solemnity of life and their own high part in it. The portraits of the fair ranged among them struck, as is fitting, a lighter note. They were prepared to smile even in the jaws of the camera, and they had done it with an earnestness beyond all praise. There are stories of the martyrs making merry upon the rack. Any who doubt them should examine the penny photograph and be confirmed in faith.

The alluring gentleman in the doorway spoke with tongues. His clients were often more at ease in a language not English. Out of the leisurely throng which spread itself over the broad sunlit street he marked with unerring instinct those who came as ready victims. It was not by any special splendour of attire, for the roadway flamed like a bed of pæonies. Probably he detected a certain bashful air,

something akin to that which betrays to the experienced eye the victims of the honeymoon. At all events, when he plunged with handbills and his voluble polyglot into the midst of the crowd rarely emerged without captives. They were not caught singly. Into the ark so to the photographer's they go in two by two. When they came out there was a certain exhilaration, a certain exultation visible in their gait, as of those who had dared a doughty deed and emerged victorious. As an innocent stimulant there are few to be getting photographed. The place of the usual headache is taken the moment when you have to look at the result. But a sufficient optimism will carry you through even that. Whatever the cause there is no doubt that getting photographed ranks high among the holiday amusements of the East End. Not only within the studio but out in the open gallant parties went under a fire. Turn out on the main roads into those exceedingly quiet, exceedingly respectable streets which surprise those who only know the legendary East End and behold an amateur directing the battery of a cheap camera upon restive friends and relations. It is hard to drive a team of giggling sisters and cousins when the small folks of the neighbourhood are commenting on the probable result. It is hard to impress the licensed jester of the neighbourhood with a sense of his responsibilities to art when he has before him such an alluring prey. With such trials as these, complicated further by the intense interest of all the matrons of the locality which brought sage heads poking out of every window to offer caustic criticism or hardly less appalling advice, it says much for the constancy of human nature that the amateur persevered. After all, it is, perhaps, as well that he should have so many excuses for the result, for the sun was blazing full into his lens. Some there were who tried more elaborate studies. In one secluded square an interesting family mounted in a pony cart were the tremulous victims of a young man with a hysterical manner and a ponderous camera that was probably the oldest member of the party. It was unnecessary and unkind that a ribald person should revive for their benefit the classic melody of "Knocked 'em in the Old Kent Road." Nearer the City there was a glimpse of an operation upon some good people in a motor-car which was long past its first wild youth. They do say that there is a thriving business in hiring motor-cars for aspiring people to be photographed in. But which of us would be happy without a borrowed plume or so?

## EXPOSURE IN TELEPHOTOGRAPHY.

(A Paper in the newly founded "Telephoto Quarterly.")

A SHORT time back a writer in the "British Journal of Photography" expressed a wish that someone would make some definite statements as to correct exposure with the telephoto lens. That is a wish which will be re-echoed by most, if not all, telephotographers, and, at the outset of this short article, I want to disclaim any idea of coming forward with those definite statements so much in demand in this interesting and important connection. All I propose, or am able, to do is to give the result of considerable personal experience and to offer a few remarks which I hope will be, at any rate, suggestive and lead to communications from other workers. Perhaps by careful comparison of notes we may, even in the course of the next few months, arrive at something really definite. Indeed, it is largely in order to assist in the gradual solution of telephotographic problems of this sort that "T.Q." has been instituted, and I earnestly trust that my readers will in this particular instance be more than ordinarily ready to allow their experience to be collated with my own.

Speaking broadly, I do not myself often make mistakes in regard to telephoto exposures, although I am constantly at work making tests with different lenses under very varying conditions. But I frankly own that my calculations are neither very definite nor scientific, and sometimes depend, perhaps more than they should

do, on that illusory condition, the appearance of the image on the focussing screen. Still, there is a sort of method in the process, and, as it seems to work, I had better, perhaps, try simply to describe it.

### Telephoto Exposures by Rule.

In the first place, it is safe to say that there is a normal condition at which one can rely pretty fully on the old rule that exposure in telephotography is the exposure with the positive lens multiplied by the square of the magnifications. Such normal condition may be stated as a clear day, a magnification not exceeding about twelve diameters, an object not more than, say, 500 yards distant, and positive lens not stopped down to a smaller aperture than  $f/11$ . Even in this normal state of affairs there is always the reservation that the exposure for the positive lens only must be calculated with reference not to the general view, but to the object which it is intended to telephotograph. Suppose, for example, we were telephotographing a ship quarter of a mile off at sea, the magnification being such that the vessel nearly filled the plate. Now the right exposure with the positive lens only at that distance might be only a two hundredth of a second, because in any general view of this sort the sea would be a more important feature than the speck of a ship. But if one only multiplied the two hundredth of a second by

the square of the magnifications, the chances are that the telephoto-graph of the ship would be considerably under-exposed. In this case the exposure with the positive lens only must be reckoned on the assumption that the ship and not the sea is the principal object. Very possibly the recalculation would mean multiplying the former result by three or four. This preliminary instance shows how difficult it is to make "definite statements" with reference to telephoto-graphic exposure.

### Exceptions to the Rule.

The first deviation from the normal that needs to be considered is distance, and here the difficulty of being definite becomes very great indeed, for the question of distance in this country is almost always complicated with that of atmosphere, and the latter to the telephotographer is often most perplexing. Speaking generally, I find from my own experience that the appearance of the object on the viewing screen is frequently a safer guide than any system of particular calculation when very distant objects are being photographed. Where the distance produces the same sort of hazy appearance as is produced in an ordinary photograph by a mist or light fog, then the exposure must be considerably reduced, though, as a rule, unless a yellow screen is used, it is not easy, however correct the exposure, to telephotograph a distant view at all satisfactorily except on a very clear day. The reduction, if made, is entirely a matter of judgment, but perhaps experiment in other hands may show that in ordinary cases of distance a modification of Howard Farmer's table can be practically applied. A second modifying factor may be aperture. As long as we do not stop the positive to a smaller aperture than  $f/11$ , or, when working at lower magnifications (*i.e.*, about 9 diameters),  $f/16$ , there does not seem to be any need to depart from the ordinary rule of f/11, with the positive at  $f/11$ , twice the exposure needed if the negative were  $f/8$ . But with very small stops the amount of light needed does not seem to decrease in due proportion. Perhaps this

is due to the fact that the present method of stopping a telephoto lens is a doubtfully scientific one. It may not be feasible in a telephoto system to place the stop at the nodal point, which is a long way in front of the entire lens. But very possibly it would be better to have it—as in the case of the Zeiss telephoto lens—between the positive and negative elements.

### Exposure according to Magnification a Fallacy.

In working at very high powers the rule as to multiplying the ordinary exposure by the square of the magnifications seems to go altogether wrong. Personally I often give only half the calculated exposure, and other advanced workers have told me that they make similar allowances. Of course, there should be a scientific explanation of this, but I cannot give it. There may be some analogy with the case of pinhole exposures in which, beyond a certain point, the rule begins to fail. Anyhow, in practice, when working above about twelve magnifications, it is as well to cut down the exposure, until, at about thirty magnifications, about half the calculated time will generally suffice.

The above may seem painfully indefinite, but there is a good deal of *mutatis mutandis* about telephotography in its present stage of development. The best that one can hope to be in this particular case is, as I said above, suggestive, and to invite other experiences.

I may conclude by saying that the use of an extended hood makes the whole question of exposure in telephotography much less difficult than it used to be. The latitude allowed when a hood of sufficient length is employed to prevent internal reflections altogether is very considerable, as any one may find out for himself by exposing two sets of plates in pairs, giving correct, half, and double exposures to each pair, and exposing one plate of each pair with the hood affixed, and one without.

The question of instantaneous exposures in telephotography demands separate consideration.

CAPTAIN OWEN WHEELER, R.E.

## THREE GOOD THINGS, AND SOMETHING ABOUT THEM.

THREE-FOUR ounces of splendid developer, clean to use, exerting no influence on finger tips, equally effective, whether films, plates, slide paper or lantern slides are being dealt with, always ready hand fresh and reliable, requiring but a moment or two to make just a few ounces of clean, cool water, crushing a couple of pills, and there is a standard solution, ready for use, and all for the proverbial twelve pence. Really it seems about as near perfection as can be imagined for the purpose of amateur photography.

It is, however, no imaginary affair at all, but another of those present-day facts we are getting rather blasé about and apt to look suspiciously at when first announced in advertisement form, with a list of special features set forth in recommendation.

Any of these new introductions pass away into oblivious forgetfulness almost as quickly as introduced, pressed on one side by other petitions for public notice, a process which is repeated time and time again, yet every now and then one stands the test of practical experience and remains, and among modern developers I fancy this introduction, "Rytol," will prove a stayer, for, having used it now for some five or six weeks on all manner of exposures, it seems to answer satisfactorily every claim possible to be made for a developer. It gives clean negatives, free from any tendency to fog, works well, gives delicate gradation and ample density, produces rich blacks when bromide papers are used, causes no trouble to delicate hands, and, withal, possesses the advantage of being one of the cheap developers we have available at the present day.

It seems a real good thing, and ought to find innumerable friends among those who require a reliable developer, put up in convenient form, and intended for universal use.

### "Carbon" Bromide Paper.

Among those who for their picture work employ one or other of the developing bromide papers there is ever the need for preserving that velvety appearance seen in deep shaded parts of the subject fully developed in print form, yet how often—when it is neces-

sary to carry the process sufficiently far to ensure having high-lights with their necessary details—do we find the darker portion bury themselves and dry out dead and disappointing.

It is all very well to preach the doctrine of making perfect negatives for each process, but precept, good as it may be, is at times difficult to carry into practice, and negatives of some subjects have a shocking habit of taking matters in their own hands and coming out not quite what we wish them to be. Anyone having to handle such negatives and make silver bromide prints from them will find the comparatively new paper, called Carbon Bromide, answer capitally, for when dry the image remains on the surface in a very satisfactory fashion, there is not that dried-in, degraded, sunken appearance we all are at times so familiar with when unsuitable hard negatives are used, and development pushed to its full extent.

For press work, when the prints are intended for reproduction, it will be found this carbon surface answers admirably; it is rich, yet with no greasy gloss, and takes pencil or powdered chalk quite kindly.

It stands between the thin film of ordinary matt surfaced papers and those with pulpy, highly glazed surfaces.

It is tough, bears handling capitally, is treated quite in the usual manner of bromide paper during exposure and development, and seems to give rise to far less disappointments after washing and drying than is often the case with other surfaces; at least, that has been my experience of it during the few months it has been used.

### A Novel Form of Finder.

When using one of the ordinary form of camera obscura finders, where you look down and view the reflected image in miniature, there is often some difficulty in seeing it clearly if at the moment you are working outside with a strong flood of bright sunlight beating down and unshaded.

It has always been more or less a trouble, under the above circumstances, to grasp rapidly and with accuracy what is the subject

included on the finder. Various devices have been adopted to try in some measure to overcome this difficulty. One of the latest takes the form of a hollow or curved plate of polished metal, which has a small spot or dot marked at its centre, then there projects above it a tiny rod, with a knob or blunt end.

To use this novel and effective aid to snap photography all that is required being to glance down, and when the rod end covers the marked centre of the polished plate it is certain that, whatever appears within the margin on the finder, will also be found on the developed negative, and relatively occupying a similar position.

It is a fresh departure, and on first handling it I was rather inclined to doubt its being any advance on others already familiar to photographers, but after using it a few times the strangeness disappeared, and it really seems to answer its purpose quite effectively. It certainly does away with any trouble caused by the glare from strong light, and doubtless will prove a welcome assistance to hand-camera workers.

It is, I understand, to be on the market in a few weeks, is cheap, made in three sizes, and may be attached to any form of hand camera already in use.

W. THOMAS.

## COLOUR PSEUDO-STEREOSCOPIC EFFECTS.

[The following curious phenomenon, described in the "Physikalische Zeitschrift," is interesting, not only because it suggests a pretty way of obtaining stereoscopic diagrams, but also because it may explain why the coloured starch grains are sometimes so noticeable when viewing Autochrome pictures in the stereoscope.—Eds. "B.J."]

If an obliterated German 10 pfennig stamp (red) is examined with both eyes through a reading glass of about 4 inches diameter, the obliteration appears to stand 2 to 3 millimetres above the stamp—that is to say, it appears to be raised above the plane of the paper. This effect does not appear with a 5 pfennig (green) stamp, the obliteration here appearing to be in the plane of the paper, or even below it. The effect is due to the colour of the stamp.

The effect does not appear when a black letter is drawn on a piece of red paper and is examined through the reading glass. Only when the paper is drawn in red and white mixed—that is to say, when one draws a fine network of red lines on white paper, and then draws a letter in black—is there any stereoscopic effect. It is especially noticeable with a wide-meshed net in those parts of the letter lying on the red lines, whereas the parts lying in between on the white ground will appear sunken in.

If also a series of concentric circles are drawn alternately with green or blue, black, red, black, etc., ink without white interspaces, when

The relief of the obliteration of the 10 pfennig stamp, mentioned at the beginning of this note, is therefore to be explained, not that the obliteration is actually raised up, but the red background, and with it the optical blanks which form the black obliteration. The relief is formed against the white parts of the paper which show through.

I confess that the explanation does not completely satisfy me. In particular, it does not explain the following phenomenon: If a large number of black, green, and red dots are made on a sheet of white paper in irregular arrangement at about 2 mm. distance from one another, and if the result be examined through a reading glass, the green dots appear in front. Behind them are the black, and still further away the red. On a black background the visual appearance is reversed.

In many three-colour prints, which are made with a coarse screen, the three colours, when examined through a reading glass, appear to be in three planes, the red on top, then the yellow, and, last of all, the blue, each being about 1.2 mm. from the other.

I may mention that the effect can be reversed if, instead of using a reading glass, two separate glasses of about 12 cm. focus are used, one for each eye. Looking through the centre of the lenses there is no stereoscopic effect, but when the outer edges of the lenses are used the effect is the same as with the reading glass; if the inner edges are used the stereoscopic effect is reversed.

With achromatic lenses the effect is not obtained, which therefore proves that the above explanation is correct.

E. GRIMSEHL.

To the above article Dr. M. von Rohr, in a later issue of the "Physikalische Zeitschrift," appends the following notes:—

Herr E. Grimsehl has called attention to a remarkable stereoscopic effect, which appears when coloured designs are examined by the two eyes through a simple reading glass. He has ascribed it to the chromatic aberration of a single lens; at the same time, however, has pointed out for the first time a still unexplained inconsistency which appears in the arrangement of coloured spots on a white ground.

This last observation also appears to be new, whilst the depth arrangement which is in accord with theory when observing coloured designs through a non-achromatised reading-glass had already been published by Sir David Brewster in 1848, and more accurately described and explained in 1851.

According to the observations of Herr Grimsehl, red, green, and blue spots on a white flat ground, when examined with both eyes through a reading-glass at increasing distances from the observer in the order blue, green, and red; and on a black ground in the order red, green, and blue. This phenomenon Herr Grimsehl has observed on a coarse three-colour half-tone.

The sketch above, by Herr Grimsehl, may be employed for the explanation. It will at once be seen that each eye looks through a prism the refractive angle of which is towards the temples. If any dark spot on a white ground is examined with one eye through a prism held in the same way, the image will be seen to be displaced—and surrounded by coloured fringes—as the result of the dispersion of the rays proceeding from the white ground. Actually a blue fringe lies on the inner—the nasal—side, a red fringe on the

viewed with binocular vision through the reading glass, the red circles will appear raised; the green, on the other hand, will be sunken in; the black circles appear also raised where their edges touch the red, and sunken in where they touch the green.

This last phenomenon leads me to suggest that the effect is due to chromatic aberration which the rays experience as they pass through the margins of the reading glass. The following diagram will explain this:  $Au_1$  and  $Au_2$  are the two eyes of the observer,  $L$  is the glass,  $A$  the object, which simultaneously emits red and blue rays, consisting of two closely contiguous blue and red points. The red rays proceeding from  $A$  take the path  $AM_1Au_1$  and  $AM_2Au_2$  into the eyes, the blue rays proceed along  $AN_1Au_1$  and  $AN_2Au_2$ . The observer transfers the point of origin of the rays in the direction of the last rays which reach the eye. The point of intersection of  $Au_1N_1$  and  $Au_2N_2$  when prolonged lies at  $B$ , that of  $Au_1M_1$  and  $Au_2M_2$  in  $H$ . From this it follows that  $B$  appears to be nearer the eye than  $A$ —that is to say, the red circles appear raised, and the green or blue sunken.

outer or temple side of the image of the spot. In the case of a blue spot, it will be enlarged on its inner side (the red fringe will be involuntarily suppressed); in other words, the corresponding image of the spot for each eye experiences a small displacement inwards, which corresponds to the nearer approach of the aerial image in binocular vision. A red spot experiences, in accordance with its spectrum, an increase towards the outer side, and this leads to an increase of the distance of the aerial image in binocular vision. It is quite different, however, with a black ground: in this case there can be no such increase, and only the prismatic, or, according to the older explanation, the lenticular, action comes into play. This latter must be greater for blue than for red, and shifts the image of the spot outwards for each eye. The result of this is that in binocular vision the blue spots are further removed.

If the spots on a dark ground are observed with the naked eye the red will appear more distant than the blue; this is to be ascribed to the non-achromatism of the human eye, a phenomenon which has been observed before, the explanation of which is not difficult, but which is somewhat too long to enter into here.

In connection with the above subject, Herr Grimsehl states that Herr F. Kohlrausch has written to him that he had called attention to a similar stereoscopic phenomenon, produced by dispersion ("Peggendorff's Annuale," 143, 144) in 1871. This was not known to Herr Grimsehl. Herr Kohlrausch used two small direct vision prisms to produce the stereoscopic effect; but he also remarked at the end of his note that the effect was also produced by a large non-achromatised convex lens.

## THE ANACHROMATIC DOUBLET LENS AS A CASKET LENS FOR PORTRAITURE.

[A writer in the current number of the "Bulletin Belge," in referring to the new type of anachromatic lens ("trousse anachromatique") worked out by M. Puyo for portraiture, gives the following formulae for constructing the lens from single anachromatic glasses, as at present obtainable. These are mounted in the barrel of an anachromatic doublet. We translate the latter name of the article, and in regard to the results produced by the semi-corrected lenses—to which MM. Puyo and Pulligny have given the name of "anachromats"—would refer the reader to our issue of March 9, 1906, which dealt with them at considerable length.—"B.J."]

RECEIVED the idea of converting my anachromatic doublet into one of the new Puyo portrait type. To do this it is sufficient to place the two meniscus lenses of which it is composed by two glasses—one positive and one negative, producing a telephoto anachromatic combination. These lenses are placed in the tube, the front lens, A, with its convex surface towards the subject, and the back lens as at B, the two plane surfaces of the lenses facing each other.

The factors which then determine the behaviour of the lens are the following: Extension of the camera (back focus); distance between lenses; maximum magnification (depending on the size of the object from one-third life-size for 7 by 5 inch plate, to one-half life-size for 10 by 7 plate); minimum distance of the subject.

In order to obtain a good correction of disturbing aberrations

magnifying lens, the smallest camera extension must be used. For a full-length figure, the distance from the subject, in the case of a sufficient correction of astigmatism, and of spherical aberration, for flatness of field, the front (positive) lens and negative lens will be plano-convex and plano-concave elements of the crown glass and the same curvature.

The formulae on which the lenses are based are as follows:—

$$x = (n + 1)f + \phi \quad T = (1/n + 1)f - \phi \quad f = \frac{\phi^2}{E}$$

where D = distance of the subject,  $1/n$  = scale of reduction, T = camera extension,  $\phi$  = focus of lenses, E = separation of the lenses.

Thus, in taking, with a tourist camera, on a 7in. by 5in. plate, with a maximum extension of 16in., a subject one-third life-size, at 6ft. (2m.) distance, the separation between the lenses being 110mm.,

$2,060 = 4f + \phi$   $400 = 43f - \phi$   $100f = \phi^2$   
for  $\phi = 225$ . These equations give  $f = 440$  and  $D = 2,065$ mm., or about 2m. (roughly 6ft. 6in.), and  $T = 387$ mm., or about 16in. As to the intensity or working aperture of this telephoto lens, it is

given by the expression  $\frac{F}{D/nd}$  where  $d$  is equal to the effective diameter of the lens.

With lenses of 61mm. diameter, working at full aperture, the intensity will be  $f/11$ . The exposure, calculated from the usual tables for plates of medium speed, should be halved for extra-rapid plates.

An ordinary lens, giving one-third life-size, at 2m. (6ft.) distance, would have to be 24in. focal length—that is to say, beyond the extension of the average outdoor 7 by 5 camera. With an ordinary lens and an extension of 16in., the scale of reduction at 2m. distance is one-ninth.

The calculation of the correction (racking-in of lens), according to the distance of the subject, is very simply made as follows,—

$$x = \frac{1}{e} \left[ 2f(1 + 1/n)^2 - \phi \right] \text{ and } n = \frac{D - (f + \phi)}{f}$$

where  $e = 57$  (for crown glass), and D is the variable.

It will be useful to calculate this correction for different distances—2m., 2½m., 3m., etc.—and to plot the distances thus obtained on a strip of paper attached to the movable tube of the lens. The correction will then be made very simply with the lens rack and pinion, or less conveniently by the camera rack adjustment.

O. LEPERSONNE.

PHOTOGRAPHIC SOCIETY.—The following lectures, which are of special interest, are included in the programme of lectures to be held on Tuesday evenings at the Royal Photographic Society's rooms during the next few weeks: April 28, "The Photo Process," by the Rotary Photographic Company;

May 12, opening of a one-man exhibition, by Furlay Lewis, with an address, to be followed by a demonstration of a new process of printing in monochrome by imbibition, by Frank Donisthorpe; May 26, a new method of securing uniformity in ozobrome printing, by Thomas Manly.

## CINEMATOGRAPH PORTRAIT PRINTS.

Attempts to apply the cinematograph in the professional practice of studio portraiture are very likely fresh in the recollection of some of our readers, who will bear us out in the statement that such attempts have hitherto been attended with commercial failure. However, it is satisfactory that the non-success of others does not deter other experimenters in the same field, and we are interested to

Fig. 1.

read in the current issue of "Der Photograph" that a firm in Hamburg, trading as the Kartaskop Company, proposes to exploit commercially the invention of a Herr H. Voss, of 110, Langerreihe, Hamburg. Herr Voss' invention, as we find it described in our contemporary, consists in a system of making a series of cinematograph records on flexible film, from which eventually a paper print is made. This print is then wrapped round the cylinder of a

Fig. 2.

viewing instrument, and on the cylinder being rotated each separate picture is brought before a lens, and a cinematographic reproduction of the living portrait obtained. It is stated that both the negatives and the viewing instruments can be produced at very moderate prices; as for the prints, they are just ordinary bromides or P.O.P.s, and can therefore be turned out at a small cost. The aim of the company will be to apply the invention to studio work by means of licences granted to photographers in given districts.

Fig. 3.

The following technical particulars will give some idea of the nature of the invention.

Fig. 1 shows one of the cinematograph portrait prints, bearing a series of exposures. Fig. 2 is an end view of the reproduction cylinder of the Karkaskop, with the print fastened thereto, and Fig. 3 is a drawing of the machine itself. In preparing the print shown in Fig. 1, the film of cinematograph pictures is cut at equal ends, and the elements of the series fastened one after another on a glass plate. This arrangement of negative pictures is then photo-

graphed to a scale corresponding to the size of the print required and any desired number of prints thus obtained. The print is rolled round the cylinder in such a way that the separate strips in rows of 10, spiral-wise around the cylinder, which is set in motion by the gear shown on the right-hand side of the drawing.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between April 6 and April 11:—

**COLOUR SCREENS.**—No. 7,629. Process for colouring celluloid for use in the production of line and point screens for colour photography. Friedrich Lehner, 4, South Street, Finsbury, London.

**SCREENS.**—No. 7,739. Method of manufacturing line and point screens. Vereinigte Kunstseide-Fabriken A.G., 4, South Street, Finsbury, London.

**COLOUR SCREENS.**—No. 7,742. Improvements in the manufacturing of line and point screens for colour photography. Friedrich Lehner, 4, South Street, Finsbury, London.

**CAMERAS.**—No. 7,862. Improvements in adapters or attachment devices for photographic cameras. George Lloyd Moore, 35, Temple Street, Birmingham.

## COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**FOCUSSED MIRROR.**—No. 1,323. 1908. The invention relates to the attachment of a hooded focussing screen and a mirror attachment thereto. Layman Magarry Sternbergh, 15th Avenue and 22nd Street, Peterson, U.S.A.

**PRINTING FRAME.**—No. 1,595. 1908. The invention consists in a printing frame, provided with improved means which enable the entire surface of the sensitive paper to be easily inspected at any time during the process of printing; means are also provided which enable the sensitive paper and also the negative to be easily removed from the frame during printing and replaced in register with each other, also for enabling a mask or masks to be applied in register with the negative and sensitive paper during the process of printing in skies and the like.

Provision is also made for a mask or masks to be placed between the glass sheets in front of the negative for the purpose of viewing. This is done by the use of a frame or carrier, at one end of which is a negative holder with clutches to same, sliding between runners or guides, also by aid of a row of metal sharply pointed perforating register pins on a metal plate or fixed to the carrier separately. John Mills, 162, Waller Road, Queen's Road, Cross, London, S.E.

**THREE-COLOUR SCREEN-PLATES.**—No. 2,213. 1908. The invention which is styled "three-colour reticules for colour photography" relates to the method of making filter screen-plates by cutting a section of a composite block of sheets of coloured celluloid. These latter are, in always the same succession of the three primary colours, placed one upon the other up to the desired height and then by pressure and heat united into a new block which is then cut crossways to the stratification into "reticules," which are then polished.

The "line-reticules" produced in the above manner can be changed into point reticules by placing the line reticules between two with parallel running lines one above the other and uniting them again by pressure and heat into a new block and dividing the same again crossways to the stratification.

On the basis of the above described process "reticules" can also be made with which positives can be produced, to be viewed by reflected light. To this end the transparency of the material from which the monochrome blocks are to be produced

must in so far be reduced that it is transparent only in a thin layer. This reduction of the transparency must, however, be effected in such a manner that the pigments added possess, viewed from above, the required luminosity. But this is only possible if a porcelain-like white substance carries the pigments.

In carrying out the process, in the first place, the transparency of the three parts of raw material for the monochrome blocks is so far reduced, say by the addition of a finely divided white stuff, such as zinc-white, that it is only transparent in a thin layer—for instance, like thin porcelain. The suitable pigments are then added. The three monochrome blocks are next produced and divided into thin layers. These layers are, exactly in the same way as described for the transparent reticule, placed one upon the other in always the same succession of the three primary colours, and then united by pressure and heat into a new block, which is now divided crossways to the stratification. The translucent three-colour reticules thus produced are polished and coated with the panchromatic layer. The negative produced by means of a transparent reticule which, together with its reticule, shows the complementary colours of the object taken when looking through it, is now copied on the above described positive reticule so that the rays pass through the positive reticule upon the panchromatic sensitised layer.

During the development of the positive the colour-elements not required for the production of the picture are covered by reduced silver bromide, and there results a photographic picture in natural colours visible from above.

This translucent positive reticule can, of course, also be transformed into a point-reticule by uniting the lines of the positive reticule exactly in the same manner as described with regard to the negative line reticule by pressure and heat into a new block and cutting the same again crossways to the stratification.

In forming the blocks from which the reticules are to be cut it is best to proceed in a manner that the thin layers are in the first place only made to be a few millimetres high, and are then pressed together into plates. These plates are then put one upon the other until the desired height of the block is reached and united by pressure and heat. By this method there are obtained perfectly straight and parallel lines through the whole block.

Robert Krayn, 2, Krausen Strasse, Berlin.

**TABLE DARK-ROOM.**—No. 10,247, 1907. The invention consists of chamber with hinged sides and provided with sleeve openings and means of admitting and discharging water. Thomas James Griffiths, 366, Monument Road, Birmingham.

**CINEMATOGRAPHS.**—No. 7,277, 1907. The claim is for cinematographic apparatus having a support provided with teeth, points, or other suitable projections, over which, after each intermittent forward movement of the film, the latter is so placed that its perforations engage with the above-mentioned projections, thus effecting an intermittent fixing of the film on the support for the purpose of preventing the thin band being drawn too far or any subsequent sliding along of the same. Stanislaus Kucharski, 58, Unter den Linden, Berlin, Germany.

**DEVELOPING TANKS.**—No. 13,650, 1907. The apparatus constructed in accordance with this invention, comprises a rectangular box or case provided with a loose cover or lid, having a flange all round. This flange drops into a gutter ledge or recess round the rim of the tank; and both are of such a depth, that when the lid or cover is in position, the box is perfectly light proof. Two opposite sides of the box are furnished with inwardly projecting ribs or flanges, so as to form a series of grooves or guides for the developing troughs (to be immediately referred to) to be placed therein. It is intended to insert at any time a less number of troughs than there are grooves or divisions, so as to be able to alter the arrangement of sequence of the troughs in the box at any momentary inspection, according to the degree of development required. The developing troughs are formed of sections in a rectangular trapezoid, one of the parallel sides of the trapezoid being slightly greater, and the other considerably less than the width of the photographic plates or films to be developed. This device ensures that the plate when inserted in the trough is always nearer the first-mentioned side; so that if the sensitised side of the plate, having the undeveloped image, is placed facing the shorter narrower side, it will have the larger or main portion of the

developing solution opposite, and with direct or unrestricted access to it; and the development proceeds more regularly.

The trapezoidal shape has the further advantage, that it enables the operator by the sense of touch, to know to which side of the trough the sensitised side of the plate should face, and he is therefore not dependent on the feeble non-actinic light when working in the dark room.

Further, this section of trough renders it impossible for the sensitised side of the plate or film to come in contact with the front

side of the trough, and be thereby damaged; and the quantity of solution required for the development is reduced to a minimum; as nearly the whole of the solution is at the sensitised side of the plate or film.

The plates are dropped into and lifted out of the trough by means of long triangular frames, termed lifters, of sheet copper or other suitable material. Frederick Woodward Branson, of the firm of Reynolds and Branson, Ltd., 13, Briggate, and 14, Commercial Street, Leeds.

**COLOUR SCREEN HOLDERS.**—No. 12,459, 1907. The patentee provides the invention of a square frame or support made of such dimensions that it can accommodate a suitable range of sizes of filters, which can be accurately adjusted to the lens or prism of varying size. One side of this frame or support is provided with a pair of vertically guided and adjustable curved clamping jaws, while the other side of the frame is provided with means for supporting and retaining the colour tank or filter. He mounts the clamping jaws on transverse bars, the outer ends of which are provided with tubular bosses that closely encircle screwed guide rods located at the corners of the frame or support. The positions of the bars—and, therefore, those of the jaws—are adjusted by means of milled nuts which engage with the screwed guide rods. The jaws are preferably formed separate from their bars, so as to enable one jaw to be replaced by another of different curvature, and they are attached to the bars by screws and slots or other suitable means. When the holder is to be secured to the mount of a prism the curved clamping jaws are dispensed with.

The filter is constructed, supporting and retaining part of the holder of an upper spring-actuated strip or bar, and a lower adjustable strip or bar. The strips or bars are provided, at their forward portions, with lips which retain the filter in its correct position against the centre of the plate holder and absolutely parallel to the lens or prism, and, at their outer ends, with tubular bosses which closely encircle guide rods located at the corners of the frame or support. Space is left between the guide rods to allow of the

removal of the colour tank or screen. The upper guide rods are plain and are surrounded by light springs which press the upper strip or bar downwards, while the lower guide rods are screwed so as to receive milled nuts and enable the lower bar or strip to be adjusted. Edgar Samuel Hunter, 26-29, Poppin's Court, Fleet Street, London, E.C.

**FILM DEVELOPING MACHINE.**—No. 31, 1908. The claim is for an apparatus for the daylight development of roll films characterised by the provision of a tape supported on spindles, and movable in either direction round a roller, the spindles being suitably suspended in a chamber about a tubular receptacle which forms the developing trough, and the roller likewise suspended near the lower part of the trough. Magnus Niell, Djursholm, Sweden.

## New Trade Dames.

**OPALANTHERENE.**—No. 299,730. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Society of Chemical Industry in Basle, 151, Klybeckstrasse, Basle, Switzerland, chemical manufacturers. January 18, 1908.

**ECONAMEL.**—No. 301,236. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Lewis Berger and Sons, Ltd., 201, Morning Lane, Homerton, London, N.E., manufacturers. March 11, 1908.

**VELBRO.**—No. 301,568. Photographic paper. Elliott and Sons, Ltd., Talbot House, Park Road, Barnet, Herts, manufacturers of photographic dry plates, films and papers. March 21, 1908.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Hypo-Alum Toning of P.O.P.

In the course of printing many thousands of postcards (says a writer in "Focus") I have had many dozens of over-printed, and thus wasted, cards. These I generally withdraw from the toning early, and they fix out warm red or orange colour. The other day I had a good few of these cards treated thus, varying in colour from bright orange to deep red.

I had an old hypo-alum toning bath made up many months ago, in which I had toned many bromide and gaslight cards. Into this bath I threw the red P.O.P. cards as an experiment. Imagine my surprise, on looking at them an hour or so later, to find that all the orange colour had gone and they were a fairly good purple tone, varying according to the colour on immersion. Any tone can be obtained according to original colour and time of immersion. I can thus use all printed cards, whether over-printed or not.

### A Dark-room Blind.

The materials necessary (writes Mr. W. Arthur Long in "Photography") are two blind rollers, with fittings and cords complete, to fit the window, but with one roller a trifle (say an inch) longer than the other, one piece of ruby fabric cut to fit the shorter roller and so form a blind, and one piece of canary fabric to fit the longer roller. Both must be made to come well down to the sill of the window, and have well weighted laths sewn or tacked into their lower edges.

The canary roller should be fixed near the top of the window frame, and the ruby roller a little below, so that the canary blind drops outside the ruby and near the window. Two pieces of thin matchboard are taken, each being cut to the length of the window casement and wide enough to overlap the perpendicular edges of both blinds when screwed one on each side of the casement. These should form a trap which will effectually stop any light from entering when the blinds are down, the blinds working, of course, inside these boards. It is well, also, to have an extra piece of board, which may be placed along the sill, but this is not necessary.

It will be obvious, now, that either the ruby or canary blind

may be drawn separately, according to the class of work to be done, or for very fast and orthochromatic plates both may be drawn.

## New Books.

"Deutsche Photographen Kalender. Part II." Edited by K. Schwieler. Weimar: Office of the "Deutsche Photographische Zeitung." Mk. 2.

Year by year we welcome the well-arranged pages of Herr Schwieler's "Kalender," which, as we mentioned some weeks ago when reviewing Part I., is one of the publications indispensable to those who have dealings in photographic matters in Germany. Part II., being the technical portion of the publication, is supplemented by the second portion now before us, which consists of a list of the photographic societies in Germany, in each case with the names and addresses of the members. These societies are arranged under (1) professional, and (2) amateurs, each list being again arranged in alphabetical order of the towns. Herr Schwieler gives a directory also of the leading photographic associations in other countries, including those in Great Britain, which are affiliated to the Royal Photographic Society. If we may judge of the accuracy of his data from the British list, the "Kalender" is remarkably free from errors. The list of photographic schools of instruction in Germany and Austria also given, after which we have particulars of the photographic press of Germany and foreign countries, and finally, and perhaps the most useful portion of the volume, a directory of the photographic trade in German-speaking countries, arranged, first in alphabetical order of the firms, secondly in a subject classification of manufacturing articles, and thirdly in an alphabetical list of towns. In each list we get a rapid review of the distribution of photographic industry in Germany. Berlin comes first with the greatest number of firms, but Dresden, which stands second on the list in point of numbers, no doubt the more important site of the photographic industry, the manufacture of cameras and papers is concentrated in its neighbourhood.

"Photographische Belichtungs Tabelle." By P. Eichmann. Berlin: Gustav Schmidt.

A useful pocket volume of an exposure guide is issued under this title. It is arranged on the basis of the well-known exposure table of Burton, but in such a way that the user is relieved from calculations. The light value for a given month and time of day is selected from a table and the necessary calculations made by a series of concentric discs at the end of the volume. The book also contains a detachable inset serving as a diary for the entry of exposures.

### CATALOGUES AND TRADE NOTICES.

THE WESTMINSTER PHOTOGRAPHIC EXCHANGE, LTD., have issued a revised and up-to-date catalogue of apparatus, accessories, and materials which they are in a position to supply. The list, which is abundantly illustrated, includes practically everything of importance at present on the photographic market, and should prove of interest to both the professional and amateur worker. The same firm has also published a list of second-hand goods, including well-known makes of cameras, lenses, enlargers, etc., which they are offering at considerably reduced prices. Both lists may be obtained from the above firm at 119, Victoria Street, Westminster, London, S.W.

"THE IMPERIAL HANDBOOK," 1908, written specially for the amateur photographer, and obtainable, post free, from the Imperial Dry Plate Company, Cricklewood, London, N.W., contains many particulars on the function of the stop, halation, fog, portraits by gaslight, orthochrome plates, gaslight and bromide printing, stains, spots, and pinholes.

GAUMONT CAMERAS.—A new list of the Gaumont Company's 5 and 6, Sherwood Street, Piccadilly Circus, W., reaches us, giving very full particulars of the excellent "Blocknotes" and "Spidos," which the makers may be justly proud. The list also specifies the firm's enlargers and other accessories for the cameras, and is emphatically a useful book of reference.

## ROYAL PHOTOGRAPHIC SOCIETY.

re held Tuesday, April 14. Mr. G. A. Storey, A.R.A., gave  
re on "Art and Photography," in the course of which he  
ed to his audience many valuable hints as to the composition  
neral treatment of a subject when reproduced by means of  
ra from the point of view of an artist.

## Commercial & Legal Intelligence.

**BIOSCOPE TRADING COMPANY.**—The partnership between  
rick Richard Griffiths, George Wm. Brown, and Arthur Charles  
way, carrying on business as exhibitors, manufacturers, and  
ers of cinematograph goods and appliances, at 5, Cecil Court,  
g Cross Road, W.C., under the style of the New Bioscope  
g Company, has been dissolved by mutual consent. All debts  
received or paid by F. R. Griffiths.

**CLAIM FOR PHOTOGRAPHS.**—In the Ilford County Court last week  
John Lyle, photographer, 855, Romford Road, Manor Park,  
Mr. Frank Miles, of 47, Aberdour Road, Goodmayes, for  
in respect to certain photographs taken and supplied. His  
said in this case he had to decide between the evidence of  
endant and that of Mr. Watts. Mr. Watts was a perfectly  
dent witness. He was sorry to have to say so, but he would  
accept the evidence of plaintiff's witness that defendant did  
the dozen photographs, and he would have to pay for the dozen.  
costs, he would pay the ordinary costs in the case, and also  
adjournment.

**EXPORTER'S BANKRUPTCY.**—At the London Bankruptcy Court.  
il 14, the statutory first meeting of creditors of James  
er Bryce, exporter of photographic accessories, 44-46,  
hall Street, E.C., was held. The receiving order was  
on March 31, upon the creditors' petition. It appears

from the debtor's statements that he began business in July,  
1896, at 23, St. Mary Axe, E.C., with a free capital of £50. He  
continued trading at that address until 1904, when he removed  
to other offices in the City. In June, 1906, he took the premises at  
44 and 46, Leadenhall Street. In February 26 last he executed a  
deed of assignment of his property in favour of a trustee, on behalf  
of his creditors generally, and the business then came to an end.  
The debtor attributes his failure to bad trade in the South African  
market, where the bulk of his business was done. No statement  
of affairs was filed, but the unsecured liabilities were estimated at  
£2,900 and the assets at £500. There was no offer of composition  
before the meeting, and, a resolution for bankruptcy having been  
passed, it was decided to leave the estate in the hands of the Official  
Receiver. The public examination is appointed for May 13.

## News and Notes.

"THE PRISM" for March deals chiefly with the subject of  
lantern projection, in regard to which it gives some useful hints,  
with special reference to a new projection lantern which is being  
placed on the market by the Bausch and Lomb Optical Company,  
for whom Messrs. Staley are the London agents. The latter firm  
will be pleased to send a copy of the little booklet to anyone  
forwarding a penny stamp for postage.

**DEMONSTRATIONS AT MESSRS. GRIFFINS.**—Messrs. Griffin, of  
Kingsway, send us particulars of the revised arrangements for  
demonstrations at their "photographic rendezvous." The fixtures  
are as follows: Every Monday at 3.30 p.m.—Velox printing by  
gaslight and modern toning methods; every Tuesday at 3.30 p.m.—  
development of "Watalu" plates; every Wednesday at 3.30 p.m.—  
"Goldona" printing (self-toning paper); every Thursday at 3.30  
p.m.—oil pigment printing (this process enables any amateur  
to produce real oil pigment prints from his own negatives); every  
Friday at 3.30 p.m.—the art of mounting photographs. Messrs.  
Griffin point out that they deal not only with the matters mentioned,  
but are pleased to give information about any photographic topic,  
and inquiries by post receive careful and prompt attention.

**A CARICATURIST OF COBURN.**—There are few worlds left for a  
man to conquer after he has been caricatured, and, indeed, it is  
said that not a few reputations have been made as well as unmade  
by the caricaturist's pencil. In America a new caricaturist has  
arisen in the person of Mr. de Zayas, who has turned his attention  
to Mr. Alvin Langdon Coburn, among others. Mr. de Zayas is a  
Mexican who has lately come to New York, and his work is said to  
be quickly challenging public attention by reason of its unique

simplicity and effectiveness. "De Zayas," we are told, "is not at  
all interested in the facial contour of a head, as the chance passer-  
by sees it, but rather does he express with line that intimate  
character which always escapes a portrait painter. Mr. de Zayas's  
portraits are epochal, in that he has evolved a style—a means of  
expression—entirely his own, and yet diversified to suit the character  
he is depicting." Mr. de Zayas has recently been photographed by

Mr. Coburn, and the caricaturist turned the tables on him in the way that is shown in the accompanying sketch.

COMING EVENTS.—A correspondent, presumably a Conventioneer who will be at Brussels in July, sends us the following:—

A charming young lady of Ghent

Was snapshotted wherever she went;

She heard t' other day

Of the P.C.U.K.,

And has ordered new frocks for th' event.

STOLEN APPARATUS.—A half-plate Sanderson camera, believed to be No. 11,955, was stolen on Saturday last from Mr. E. H. Atkinson, 39, Warwick Road, Ealing. Also taken with it were six double slides, the whole contained in yellow leather, lock case, with shoulder strap. A Staley Planastigmat, 5½ in., No. 30,306, was also taken. Anyone who may come across any of these goods is requested to communicate with the police or with Mr. Atkinson.

A LARGE EXHIBITION of Kodak pictures was given at the Assembly Rooms, Bognor, on Monday, April 13, to Thursday, April 16. The enlargements shown comprised work by many well-known amateurs, including her Majesty the Queen. Mr. J. W. Eadie gave his popular lectures, "Pictures and Picture-making with a Kodak," "The Queen of Hobbies and the Hobby of Queens," and, by special request, "The Kodak in Japan," illustrated by slides coloured by native artists. Professional photography was represented by Mr. Goodyer, of the Goodyer Studio, 33, High Street, Bognor, who showed an artistic screen of portraits, including his recent photographs of Lady Rachael, the daughter of her Grace the Duchess of Norfolk, also the Hon. Mrs. Drummond and children, taken by command of her Grace at Arundel Castle. In conclusion, a word of praise must be given to Mr. E. Lawrence Wood, the local dealer, for the care taken to ensure complete success and pleasure to his visitors.

## Correspondence.

### THE DAYLIGHT SAVING BILL.

To the Editors.

Gentlemen,—I see in your influential journal of the 10th you refer to a statement that the Daylight Saving Bill is dead. The statement is wholly erroneous. The Bill was read a second time, amidst cheers and laughter, on March 26, and referred to a Select Committee to consider the practicability of the proposals, and the Committee, nine in number, have been designated, and will meet and take evidence after Easter. The Bill is supported by 180 members of the House and a host of eminent and practical men outside Parliament. Declarations in favour of it daily pour in. You also state that the Bill projects putting all clocks forward in April and backward in September. That will probably be the effect of the law, no doubt, but the Bill itself says nothing about clocks or watches, or candles or daylight. It merely proposes that four Sunday morning hours in April shall be only forty minutes long, and four Sunday morning hours in September shall be eighty minutes long. The people can alter their clocks and watches accordingly if and when they like. Very thankful for your notice, if you will kindly accept this correction.—Yours truly,

House of Commons.

April 16, 1908.

### THE PORTRAIT POSTCARD.

To the Editors.

Gentlemen,—I regret to take up your space again, but I want a word with "Arch Fiend," the solitary champion of the "touters."

His somewhat bullying letter would have been more convincing if he had told us what his price for postcards was. Anyone can expose four dozen plates per day on 1s. 6d. per dozen cards, possibly taken "on spec.," and "show you a proof to-morrow." It may be good for dealers, but Heaven help the rest of us.

He also takes exception to the phrase I used—"battening on the provender provided for others"—and says I might as well say, "Shop anywhere else if you dare." This is quite beside the question. With established competitors, I know they have to pay rent and taxes the same as I do, but "Arch Fiend" wanders up and down the country, injuring all, accepting any price he can get, and any cellar or garret is good enough for him to develop his plates and "gaslights" in.

Now I appeal to self-respecting photographers—men who wish to pay their way squarely, live decently, keep up a respectable shop and studio, educate their children, and perform their duty as citizens—can they do these things if their means of living are debased by unprincipled people whose only care is to live from day to day? The future of professional photography, as it applies to the smaller members of the trade, will be ruinous if something is not done and done quickly.

The idea of "Another Country Pro." of taking character into consideration when granting licences is excellent, and would, I think, be a great protection, especially if a portrait of the licensee were attached to every permit.

There must be, in fact, a photographic "black list," and licensees rigidly refused to those on it. In case of partners and companies, the act of one member should condemn the whole firm until he was expelled.

I have been a member of the Professional Photographers' Association since its commencement, and last year pointed out to the secretary how useless the Association was to countrymembers. His reply, of course, was conciliatory, but not convincing. If the association will take up this question to a successful issue, I will predict a doubling of membership within a year.—Yours faithfully,

FAIR TRADE AND FAIR PRICES.

To the Editors.

Gentlemen,—I have no doubt it pays a photographer to turn out postcards at 2s. 6d. or less per dozen in large towns or holiday resorts where the studio is kept going all day long. But in a country town where sitters are limited it appears to me foolish to enter into competition with a rival who thinks that by cheap work he will capture all the trade. His expenses are probably just as much as your own, and in due course he will feel the effect of reduced prices. I presume that none of us take photographs for the benefit of the public, but so that we may scrape together a living and keep out of the county court and workhouse. We fix our prices accordingly, and any reduction on these prices means a benefit to the public at our expense.

My experience of photography is that customers will come to you if they know you are going to take trouble and do your best to please them, and you cannot do this, neither can they expect it, for 2s. 6d. per dozen.

With reference to the letter from "Brains," if he had to photograph a full-length of a countryman in a ready-made suit, or the average servant girl in her Sunday best, he would find some difficulty in putting into practice his artistic knowledge gained by lovingly studying portraiture at the picture galleries.

ANOTHER COUNTRY PHOTOGRAPHER.

To the Editors.

Gentlemen,—I am an artist (oils), a photographer, and an old member of the London Fabian Society. On page 17 of the Fabian Essays, "Economic Basis of Socialism," G. Bernard Shaw says: "We now see how man's control over the value of commodities consists solely in his power of regulating their supply." He says: "If there is double the quantity of an article over the demand, and the first lot (of umbrellas) is marked 15s. and the second lot, same quality, is 8s. 6d., the public would buy all those at 8s. 6d., and so the first would fall to the same price." A portrait or group postcard is virtually a photograph mounted, and in selling these at a low price in a small quantity the sale of higher-priced work, same size, is in danger. We must regulate the supply and control the price of photographic work by combination in the form of a trade union. No under-cutting, but a minimum price. Can we persuade the Press to consult our union list and to omit to publish amateurs' (not union) names under photographers, and paying them a much smaller fee, and could not our executive act as a press agency, submitting

to all the papers? They might also approach all the trade manufacturers and request that only those on the union list should full trade discount. They might purchase, at wholesale rates, half of members, or help in the purchase of expensive apparatus. Qualification for joining the union would be efficiency, according to work taken up, proved by work submitted, facilities might be offered by leading members, or by the State, in the instruction of members. Amateurs turning professionals—i.e., unionists—, of course, be eligible. The Legislature might favour us, as all other organised labour. The State could be persuaded a great deal by opening out fresh avenues of work with strong inducements in connection with art, technical, trade, and life matters, as well as education in general. I am a member of the Professional Photographers' Association, but the handbook and circular are the only fruits in about six months.—I am, faithfully,  
SIDNEY A. DRIVER.  
Wey, near Colchester.  
April 20, 1908.

I refer this correspondent also to the annual report of the Association, printed in our issue of March 27, for a refutation of his charge of activity against the P.P.A.—Ems. "B.J."]

To the Editors.

Gentlemen,—I wonder if any of your readers have noticed the correspondence between Mr. Butt's excellent articles and the correspondence about postcards in the "B.J." recently. By a strange coincidence we have seen what a photographic business ought to be in and what it actually is to many in practice.

It is very sound odd to your correspondents to hear of one who does postcards occasionally and makes them pay. Details are necessary, except that I get 5s. for a dozen and 3d. each for copies. The fact is in my case they are a means to an end rather than the end itself, and it is because photographers have it that they have become such a nuisance. For the life of a man cannot see how anyone is compelled to do postcards at 2s. 6d. a dozen. There must be something wrong with their methods. I have it in their power to say "No!" but do not, in fact. I believe they ever really look into it further than "that up to date postcards are 2s. 6d.," hence they must do them at that if possible.

After all, there is another aspect which ought to appeal to our patrons benefit? I say most emphatically, No! not present conditions. How can they? But they ought to, and so they would under proper conditions, and so would we photographers too.

My correspondent, "Brains," shows his inability to grasp a elementary fact that postcards are being done from negatives by many leading photographers, and there are many "Old Hands" to be had for the large sum of twopence. The London photographer, who employs him to retouch his special negatives, is so ashamed of himself. But, there, it may be only a bad job. Who knows? When travellers tell us they never have been put on the market, it is evident manufacturers are alarmed, so poor "Brains" had better come to earth on with his "something in the city."

Will we realise it is not so much because postcards are they are so popular, but because they give pleasure?

Thank you, gentlemen, for the kind interest you always take on behalf.—Yours, etc.,  
R. R.

To the Editors.

Gentlemen,—Allow me to congratulate the photographers who have just awakened to the fact that even in photography some protection is needed whereby it is possible the workers may earn a living wage, and the sooner photographers recognize the fact that they are tradesmen and are working for a living rather than for themselves. The miner, the cotton weaver, the carpenter, the bricklayer, the engineer, the mason, the barber who scrapes your chin at a penny a time have means to which they subscribe weekly, enabling them to become capable of looking after their interests. But the photographer poses as an artist, a gentleman of a higher social position, fraternise with a common labourer, a man who works for his living? His stiff neck and high aristocratic bearing

would be disgraced, and yet, forsooth, what is he, and where is his picture capability without his camera? He must carry it with him exactly as the bricklayer carries his trowel or the carpenter his saw, and these men, with the addition of the miner, the cotton operative, the ironworker, and even the poor shop assistant, are the very means whereby he attains his livelihood. These men protect themselves and try as hard as possible, paying as much as 6d. per week out of their hard-earned wages to capable agents, who not only air their grievances on the public platform, but use every means in their power to help the workers to a living wage, exposing blacklegs, and meeting employees in a firm and straightforward manner. Then why cannot photographers do this thing? Surely there are sufficient of us to make some movement to improve the present trade depression brought on, not only by the postcard evil, but also by the injudicious use of the free coupon, enabling a few to rise at the expense and degradation of their fellow-men. I myself am both ready and willing to support any movement within reason, but I think the £10 licence is without the pale of scores of photographers who have followed photography as a means of livelihood, as one of your correspondents says, for over 20 years. Hoping some suitable arrangement may still be arrived at whereby something will be eventually done, I remain, yours truly,

HARRY PARKER

(A hard-working photographer).

89, Smith Road, Orrell Post, near Wigan,

April 21, 1908.

W. WATSON AND SONS, LIMITED.

To the Editors.

Gentlemen,—We should be glad if you would kindly bring to the notice of your readers the fact that the business which has hitherto been carried on at this address, under the style of W. Watson and Sons, has, to facilitate the adjustment of family interests and to enable us, by the extension of our manufacturing facilities, to provide for the growing demand for our goods, been registered as a private limited liability company.

There will be no change in the control or management of the various departments, all of which will be carried on as heretofore. The registered office will be 313, High Holborn, W.C.—Yours faithfully,

W. WATSON AND SONS, LTD.

313, High Holborn, London, W.C.

April 16, 1908.

PHOTOGRAPHIC INSTRUCTION IN MANCHESTER.—Prospectuses from the Municipal School of Technology, Manchester, inform us of the classes just commencing in the "Photography and Printing Crafts" departments, presided over by Mr. Charles W. Gamble. Many readers of these lines who are within easy reach of the northern capital will be glad to note that a course of lectures of a special character has been arranged, which will deal with different subjects of special interest to pictorial workers. The lectures will in all cases be devoted to the practical aspects of the branches dealt with. The course will consist of eight lectures, which will be fully illustrated by examples and other demonstrations. The syllabus is as follows:—May 5, Platinum Printing, Mr. C. F. Inston; May 12, The Hand Camera and its Use, Mr. F. Fielding; May 19-26, Lantern Slides for Pictorial Purposes, Mr. James Shaw; June 2, Carbon Printing, Mr. F. Fielding; June 16, Stereoscopic Photography, Mr. F. Eastwood; June 23, Oil Printing, Mr. C. F. Inston; June 30, The Preparation of the Negative and Control in Printing, Mr. T. Lee Syms. In addition to these arrangements a note should be made of Mr. Gamble's course of eight lecture demonstrations on the preparation of orthochromatic dry plates and the principles underlying their production and use, together with the making of correction filters for the same. The operations will be fully demonstrated, and the use of the special testing apparatus will be shown and explained. The syllabus is: The teaching of the spectrum camera; gelatinobromide of silver and its behaviour towards light of different wavelengths; spectrum colours and pigmentary colours; the sensitising action of colour stuffs; making and testing orthochromatic plates; colour sensitometers; laboratory and studio methods of testing; making and adjusting colour correction filters; the rendering of colour luminosities into monochrome. This course commences on May 7, and the fee for the eight lectures is 5s.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. The unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

**J. J. Forsyth**, 57, Cowgate Street, Kirkintilloch. *Photograph of Magic Ruby, Performed by St. Andrews Musical Association, Kirkintilloch, March 16, 1908.*  
**G. Toulmin and Sons**, 127, Fishergate, Preston. *Photograph of St. Andrew's Boys' Football Team, Preston. Photograph of St. Walbuge's Boys' Football Team, Preston.*

**J. A.**—Messrs. Jonathan Fallowfield, 146, Charing Cross Road, London, W.C., make a specialty of these goods.

**J. W. M. MASON**.—For ordinary plates, tartrazine and Rose Bengal. For ortho. plates, these two dyes, with also methyl violet. For panchromatics, acid green, naphthol green, and tartrazine. But you had best get the dark-room safelights obtainable commercially.

**HOOSIER**.—Use thin bluish engineers' tracing cloth, obtainable from firms such as J. Halden and Co., Great Chapel Street, London, S.W.

**Dextrine Paste**.—In making a mountant of white dextrine I find the paste reddens litmus paper, and therefore fear it would be unfit for photographic use. Would neutralising with bicarbonate of soda render its use safe, and what will be the best preservative for the paste?—**E. R. S.**

Dextrine, whether white or yellow, is almost invariably acid, and therefore needs to be neutralised before use. Bicarbonate of soda can be used for the purpose. The best preservative is oil of wintergreen or thymol.

**REFLEX CAMERAS**.—I am desirous of obtaining working drawings, dimensioned sketches or scale drawings, of the shutter and mirror mechanism of a reflex camera, such as is used on most of the modern cameras of that type. Could you tell me, through the columns of your paper, where I could obtain these, or, if not, give me some sketches in your paper?—**T. F.**

None are obtainable, except in the patent specifications relating to reflex cameras. We advise you to consult the official classified abstracts of patents for the last year or two.

**TITLES ON POSTCARDS**.—(1) I should be greatly obliged if you would be kind enough to tell me how postcards are titled, particularly in the plate-sunk ones, black lettering on a pure white ground. (2) Also where could I obtain a die for plate sinking and cost of same.—**PLATE MARK.**

(1) We have repeatedly answered this query, and would refer you to our issue of July 12, 1907, for details. In brief, the method is as follows:—The words forming the title are set up in type and photographed on a process plate. The subject negative having been made with a clear margin round it, a strip of the title negative is laid down on this margin by stripping, and the clear margin then filled up with "photopake" or other blocking-out mixture, except over the strip of title, which is made dense enough in the first instance to print white. (2) Any large photographic house, such as Jonathan Fallowfield, and others.

**GOLD CHLORIDE**.—I should feel obliged if you would kindly let me know how many grains of bi-chloride I should obtain by dissolving half a sovereign in acids.—**J. T.**

There are 56 grains of pure gold in half a sovereign, so that you should obtain a little over 100 grains of gold chloride.

**A. G. C.**—The print is evidently on collodio-chloride paper toned with gold and platinum. Almost any of the many C.C. papers will give you this result.

**T. M.**—One formula which has been recommended is: White pale yellow shellac, 300 parts; gum elemi, 30 parts; Canada balsam, 50 parts; methylated spirit, 1,000 c.c.s.

**INDIA-RUBBER SOLUTION**.—Can you please tell me how to make india-rubber solution? I want it for temporarily attaching masks to negatives. I have tried to dissolve the rubber in benzole, but cannot get it to dissolve; although it has been soaking for fortnight it is still as hard as ever.—**R. SMITHERS.**

You have evidently been trying to use the wrong kind of rubber, viz., vulcanised rubber, which is not soluble in benzole. You require what is known as masticated rubber. Instead of dissolving the rubber yourself we should recommend you to purchase tin of solution at one or other of the shops where india-rubber goods are sold, and thin that down to the consistency you require with benzole. This will be less trouble than dissolving solid rubber. For the purpose you require you would find solution sold in tubes, for the repair of cycle tyres, very convenient. You can squeeze a little out on to the negative where required, and then attach the mask.

**LENS QUERY**.—I have lately been given a half-plate camera. It is a very old one, but very well made. It is fitted with a still lens, bearing the name of "A. Ross." The camera is a landscape one, and I shall only use it for outdoor views. Would there be any very great advantage in replacing the present lens by one of anastigmatic kind? I may say that I know nothing of optics, but am troubling you with this question. Naturally, I do not wish to lay out money, which is none too plentiful with me, unless I could ensure getting better results with it than with the present lens.—**X. Y. (Hants.)**

If you are going to confine your work entirely to landscapes cannot have a better lens for the purpose. The disadvantage of the single landscape lens is that, in photographing buildings, which happen to come near the margin of the field are slightly distorted—i.e., curved inwards. Also the lens is slow, by reason of the comparatively small apertures at which it has to be used. For pure landscape work some of our best men of the past generation used the single lens in preference to all other forms.

**DISSOLVING SHELLAC**.—I shall be thankful if you will kindly enlighten me on the following matter: A year or two ago I made a negative varnish according to one of the formulæ given in "Almanac," and excellent it proved. Last week I attempted to make up some more according to the same formula, but I could not get the lac to dissolve, and it was sent to me as the best varnish. It softened somewhat by long digesting in the methylated spirit, but I could not get it to dissolve at all. What can I do?—**AJAX.**

The fault is in the lac. It has become "perished" by keeping. Bleached lac is very liable to get insoluble in spirit by long keeping, more particularly if it is not kept in a somewhat moist condition. The only thing you can do is to get another sample, get it, if possible, direct from a lac bleacher, so that you can ensure that it is freshly bleached. When the supply is drawn from the shop there is no telling how long it may have been in stock.

\**NOTICE TO ADVERTISERS.*—Blocks and copy are received only to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

the Oil Process.—Mr. Robert Demachy reviews the exhibition of prints now being held at the Photo-Club de Paris. (P. 340.)  
 an exhibition of bromoil prints opens on Monday next at the house of THE BRITISH JOURNAL OF PHOTOGRAPHY.  
 the amalgamation of "The Amateur Photographer" with "The Photographic News," and of "Photography" with "Focus" has been generally known within the past few days. (P. 337.)  
 the Hinton Memorial Fund has now reached a total of £368. (P. 345.)  
 the Modern Studio.—Mr. Butt's current article continues the series on the furnishing and decoration of the studio. (P. 341.)  
 the chief facts of foreign and international copyright form the subject of this week's (concluding) "copyright conversation." (P. 344.)  
 print trimmer and a self-portrait shutter are among the patents he week. (P. 345.)  
 the portrait postcard and the modified Farmer's reducer of Mr. Welborne Piper figure in our correspondence columns this week. (P. 349.)  
 some editorial notes on the procedure to be adopted by photographic inventors when taking out a patent are given on page 338.  
 fraudulent enlargement canvasser received two months' imprisonment with hard labour at Leicester last week. (P. 348.)  
 consular report states that Mexico offers good prospects for photographic entertainments. (P. 344.)  
 exposure in enlarging. Mr. J. Nixon writes further on his recent article on page 350. Our comments appear on page 338.

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

Mr. J. C. Warburg contributes a report of a recent Autochrome exhibition by M. Meys, of Paris, of whose methods some details are given. (P. 33.)  
 M. Didier, the inventor of pinatype, has recommended his process as a practical means of preparing paper prints from Autochrome transparencies. (P. 35.)  
 Mr. E. Stenger and Herr F. Leiber contribute some notes on the use of the Leuco-bases in the reproduction of Autochrome pictures. (P. 34.)  
 modified method of assembling the three-colour components in the Rotary carbon process have been published. (P. 37.)  
 the translation of a paper on the chemistry of the bleach-out process is given on page 38.  
 the recent results on the gradation of plates exposed to light of different colours have been published by Dr. Lohmeyer. (P. 40.)

## EX CATHEDRA.

**Bavaria in bromoil.** An exhibition illustrative of the Bromoil process will be opened at "The British Journal of Photography" on Monday next, May 4, and will remain open until Wednesday, May 27. The exhibition consists of bromoil prints from negatives made in Bavaria by George E. Brown. "Straight" enlargements of these, made by Messrs. John J. Griffin and Sons on their matt "Snow-white" bromide paper, have been treated by Mr. Welborne Piper, the inventor of the Bromoil process. The final and vital operation in the production of the exhibited pictures, namely, the pigmenting, has been done by Mr. F. C. Tilney, to whom the lion's share of any pictorial result obtained must therefore be assigned. Each visitor to the exhibition will be presented with a catalogue of the prints and a brief instruction and formula sheet by Mr. Piper for the working of the process. The exhibition, as announced elsewhere in this issue, is open daily from 10.30 to 4.30 (Saturdays 10.30 to 12.30).

**The Colour Exhibition.** We would again draw attention to the forthcoming exhibition of the Society of Colour Photographers, which is to be held during June at the house of the "British Journal." The last day for entries is May 12, and for exhibits, May 15. The entry form should be sent to the Honorary Secretary of the Society of Colour Photographers, Mr. Henry J. Comley, Surrey House, Stroud. The exhibits themselves should be addressed to Mr. Comley at 24, Wellington Street, Strand, London, W.C. It may be intimated that, as at the exhibition of the Society held six months ago, effective provision will be made for the display of Autochrome and other transparencies, of which it is anticipated there will be a particularly fine show.

**Exeunt "Focus" and the "P.N."** Readers of our four weekly contemporaries have no doubt been somewhat astonished to see the announcements of two events, the imminence of which had been known in certain circles for the past week or two. We refer to the amalgamation of (1) "The Amateur Photographer" and "The Photographic News," and (2) "Photography" and "Focus." Messrs. Hazell, Watson, and Viney have purchased the "Photographic News," which from May 12 they will issue as "The Amateur Photographer and Photographic News." In thus acquiring a journal which for a few months short of fifty years has appealed to amateur photographers, they secure the adherence of a large body of readers, and, at the same time, have arranged with Mr. F. J. Mortimer, for the past two years editor of the "News," to edit the joint publication. In the case of the other amalgamation, the five-year-old "Focus" has been purchased by Messrs. Iliffe and Sons, Ltd., who will unite

it with "Photography," under the title "Photography and Focus," commencing also from May 12. Mr. R. Child Bayley will continue in the occupancy of the editorial chair in Tudor Street. These changes appear to have been received with equanimity, not to say satisfaction, by readers, advertisers, and distributors. All, we think, were agreed that there were too many photographic journals. In the new circumstances our elementary friends can take their pick of the two reconstructed journals, while we of the "B.J." shall continue in that policy of dealing fully with technical and commercial matters which has been adhered to in these pages for the past fifty-four years.

### Exposure in Enlarging.

Our note on Mr. Nixon's method of adjusting the enlarging lantern has drawn a reply from that gentleman in which he assumes that the lens to which we referred in our note was a lens of  $f/4$  aperture, and therefore of too large a diameter to render his rule workable. He arrives at this conclusion from what he describes as "internal evidence"; but, whatever this may be, it has misled him, for the lens in question was an 8 in. R.R. working at  $f/8$ . He suggests that stopping down to obtain even illumination would have made his theory work all right; but, as a matter of fact, stopping down makes the illumination even worse. It may be news to Mr. Nixon to learn that with big lights it is generally easier to obtain good illumination with large apertures than with small ones, and that even if his theories with regard to aperture held good they would be impracticable, for a lens of small aperture is next to useless for enlarging purposes. With incandescent gas an  $f/8$  lens such as we used is too slow for anything but a small degree of enlargement from a thin negative. Using an  $f/4$  lens of 6 in. focal length it is possible to get good illumination with the image of the light on the projector, but this is only because there is considerable latitude of adjustment with the big light and a lens of such large aperture. Mr. Nixon's adjustment can therefore be carried out in circumstances in which his rule of exposure cannot apply. Mr. Nixon now goes so far as to say that his rule of exposure will hold good for any light and any lantern if one stops down until the disc is even. We would suggest that he tries this theory in practice with his own lantern. He also comes to the comfortable conclusion that because his rule of exposure has not been worked out before, no scientific man has ever taken the trouble to calculate the relations which ought to obtain between condenser and projector to secure the greatest efficiency in the instrument. This is a very big assumption. Mr. Nixon would be far nearer the truth if he suggested that scientific men long ago found out that theories worked out on paper had an inconvenient habit of breaking down when practically applied to the lantern. He evidently has not had much experience of enlarging, otherwise he would appreciate the value of small powerful sources of light, such as the arc, with projecting lenses of large diameter, with which arrangements his theories fail altogether. The total absurdity of using an arc-light and stopping down the lens to make his theory of exposure workable has evidently not occurred to him.

### The Theory of Vision.

A little time ago we drew attention to the fact that the theories of stereoscopic and binocular vision had been greatly confused by the unwarrantable assumption, by Brewster and others, that young children, and new-born animals generally, can perceive distance as readily as adults. This idea has led many to look upon all our visual powers as automatic or "inborn," and to neglect what is the obvious truth, viz., that we have to learn to see just as we have to learn to speak or walk. Why Brewster should have ever lent his support to such a theory is incomprehensible, for

the fact that very young children have little or no control over their vision was well known in his time and long before. Our attention has been directed to an interesting note on this subject in Pepys' Diary, written on May 2, 1659, while on board the "Charles," from which ship Charles II. landed in England the next day. It appears that Pepys had been entertaining to dinner in his cabin a number of friends, including Dr. Scarborough, physician to the King, and some other doctors. The conversation evidently turned on the selfsame subject that we are often discussing 250 years later, that is, upon vision; for when all the doctors again assembled in the same cabin to supper our good friend Pepys "put Dr. Scarborough in mind of what I heard him say, that children do, in everyday's experience, look several ways with both their eyes till custom teaches them otherwise; and that we do not see but with one eye, our eyes looking in parallel lines. The last part of this sentence suggests a resemblance to the theories of vision of Drs. Wells and Le Conte. Dr. Scarborough is described in a footnote as a learned and incomparable anatomist, and if he ever produced any books upon vision they must be well worth referring to.

### Colour Pseudo-Stereoscopic Effects.

Some curious and interesting effects are produced when colours are observed through single non-achromatic lenses. These were explained by Herr E. Grimsahl in Dr. M. von Rohr's articles that we reproduced in our last issue. Very similar effects (as a correspondent pointed out on another page) are, however, sometimes observable without the aid of a viewing lens, for colour patches projected on to a lantern screen often show a very remarkable amount of relief. In Dr. Mees' lecture on "Screen Plate Photography," given a short time ago at the Royal Society of Arts, a number of colour charts were shown upon the screen, and in these the colours showed a very marked difference in apparent distance. In several cases the red appeared to stand out several feet in front of the screen, and such an effect is at first sight not quite easily explained as the ones that depend on the use of uncorrected single lenses. The fact that the eye is not achromatic is, however, the real cause in this case. If a red patch and a violet patch are on the screen at the same time, then if we accommodate our eyes to focus the violet the focus for the red is behind the retina or just where the focus of a nearer object would be. In changing the accommodation to focus the red the change is just the same as that which would be necessary to focus a nearer object; therefore the sensation of nearness is aroused. The effect is often very obvious in the case of bright red lettering, especially when it is on a very dark or black background.

### SOME HINTS TO PHOTOGRAPHIC PATENTEES

In our issue of September 27 of last year we dealt with some of the more important points of the then new Patent Act, which became law on the first day of the present year. As we then pointed out, the Act was a highly protective measure in disguise, and one of the first salutary results of its becoming law has been the erection of factories in this country by Continental manufacturers, in order to permit of their complying with the clause in the Act which makes it necessary for a patent to be worked in the country in order to assure its maintenance. It is not, however, with this side of patent law that it is our intention to pen a few notes on the present occasion. Our object is to give some few hints for the benefit of those who not infrequently address themselves to us for information on patent matters. Very frequently our advice is bound to be in the nature of discouragement of the would-

patentee, for the reason that, unless an invention has very great commercial application, the cost of upholding it becomes a serious drain on persons of small resources, and, therefore, the policy of patenting should be postponed until the invention is at any rate in such an advanced state that it may be quickly disposed of or commercially applied. Further, the inventor, not to say the photographic inventor, is usually a very enthusiastic person—a glance through the patent specifications which are published shows that he cannot be anything else—therefore, it may be fitting to give one or two hints of the ordinary method of procedure. As is well known, the Patent Office fee for granting a provisional specification is only £1, although, unless the inventor draws up the specification himself, he must, in addition, pay the agent's fee, which may be moderately placed at from two to five times that amount, the sum depending on the amount of work entailed in drawing up the patent. We are sometimes asked whether it is worth employing an agent or not, and our reply usually is that in the case of inventions which promise to be commercially valuable the money spent on having the wording of the claims properly drawn up is certainly well spent. We may, however, draw attention to one or two of the points which must be observed by an inventor making out his own specification. Using the official form, obtainable from Southampton Buildings, he must give a declaration to the effect that he is in possession of a certain invention, the nature of which he must also give, and in regard to which he must claim to be the true and first inventor. This declaration is accompanied by either a provisional or complete specification; a very general course is to apply for the first instance for a provisional protection, the procedure as to which is as follows:—A form A and two forms must be obtained from the Inland Revenue office, the High Courts of Justice, Strand, or from the chief post office in most large towns. One of the B forms must bear a stamp, and may be purchased in this state, or the stamp impressed after the form has been filled up. The form A, when filled up, is a declaration that the applicant is the true and first inventor. The form B must be filled in duplicate, and one of the B forms must bear the stamp; the other need not be stamped and must describe the nature of the invention. Full working details need not be given here, but only a descriptive outline. The forms are placed with the Comptroller, Patent Office, Southampton Buildings, London, W.C.

After the application has been accepted the invention is protected. But within six months of the date of the application the complete specification must be lodged, otherwise the application is deemed to be abandoned. During that period the inventor, as his invention is protected, has the opportunity of improving or perfecting it; during the time he can negotiate for its disposal, or make arrangements for its working, as he may think fit. It will be seen that there is some advantage in lodging a provisional specification prior to the complete one. It is just being mentioned that the complete specification must be left within six months of the application. The Comptroller, however, has the power to grant an extension of the time on payment of a fee, but in no case for more than a month.

For the complete specification two forms C are necessary, and they must be filled up in duplicate, as were the provisional ones. One of these must be stamped with a stamp, but, like the provisional, it may be filled up and stamped afterwards if desired. If the patent is, say, for a piece of apparatus, the specifications should be accompanied by drawings, which must be on white hot-pressed or calendar drawing-paper. The sheets must measure thirteen inches from top to bottom, and be either

eight or sixteen inches wide, and have a border line half an inch from the edge. These dimensions must be adhered to, as the drawings have to be reproduced in the published specifications. The Patent Office will supply, free of charge, a specimen drawing on application to serve as a guide. The complete specification should be drawn out with great care. It must fully describe the nature of the invention and the manner in which it is to be performed. Such details must be given as will enable any ordinary craftsman to work the invention after the patent has expired. This is, practically, one of the conditions upon which the monopoly of a patent is granted. Unless such details are given the patent can be refused by the Comptroller; or it may, in the case of litigation, be set aside on the ground that sufficient information was not afforded to enable an ordinary workman to carry it out from the directions given in the specification. If the forms B and C are not large enough to contain the description of the process or apparatus, they may be continued on ruled foolscap paper with a margin of two inches on the left-hand side. Suitable paper for the purpose may be had at most law stationers under the name of "continuation paper."

The complete specification must end with a distinct and proper statement of the claims. They must form a brief statement of the items which constitute the invention, and care should be taken that these claims contain neither more nor less than it is desired to protect in the patent. Any number of claims may be made, but it is unwise to make more than are actually necessary to protect the patent. It should be mentioned that if, in a case of litigation, one of the claims is proved to be bad, the whole patent becomes null and void. In America the case is different. There, if twenty claims were made and nineteen of them proved bad, the patent for the twentieth would stand. Hence it will be recognised that the fewer claims made, so long as they are sufficient, the better.

After a complete specification is advertised as accepted it is open to inspection by anyone on payment of a small fee. But after two or three weeks it is published, and may be seen in the library at the Patent Office free of charge, or may be purchased for eightpence. Within two months of the specification being advertised as accepted, and its being sealed, anyone may oppose the sealing on any of the following grounds. We here quote from Section 11 of the new Act:—“(a) That the applicant obtained the invention from him or from a person of whom he is the legal representative; or (b) That the invention has been claimed in any complete specification for a British patent which is or will be of prior date to the patent the grant of which is opposed, other than a patent deposited pursuant to an application made more than fifty years before the application for such last-mentioned patent; or (c) That the nature of the invention or the manner in which it is to be performed is not sufficiently or fairly described and ascertained in the complete specification; or (d) That the complete specification describes or claims an invention other than that described in the provisional specification, and that such other invention forms the subject of an application made by the opponent in the interval between the leaving of the provisional specification and the leaving of the complete specification; *but on no other ground*” (the italics are ours). From this it will be seen that prior publication or use is not a ground for opposition, though it would invalidate a patent, even if sealed.

At the sealing of a patent a further fee of £1 has to be paid, as an investigation fee as to whether the invention has formed the subject of a patent during the past fifty years. But, as we said in the previous article, photographic patentees will do well to make independent investigations for themselves; and for this reason. An

invention may have been published and described in the "Journals," but not patented, yet that would be sufficient to upset a patent, if contested, notwithstanding that one has been sealed for it.

It was mentioned above that if any one of the claims

made in a specification was found to be bad the whole patent goes. A patentee can at any time amend his specification by way of disclaiming any portion of it, but at the same time anyone is at liberty to oppose the amendment.

## AN EXHIBITION OF OIL PRINTS AT THE PARIS PHOTO-CLUB.

It is a pity that one-process shows are so rare. There is no better opportunity for judging the merit of a process than when two or three hundred examples of its possibilities are held up to criticism in the same room, without the disturbing neighbourhood of other mediums. For this reason the international exhibition of oil prints now open at the Paris Photo-Club's rooms—44, Rue des Mathurins—will interest, not only the amateur in oils, but all men of pictorial feeling. For the oil process is surely a severe test of the aims and capabilities of the man who handles it. With gum-bichromate, an indifferent photographer, devoid of artistic feeling, might, by the pure chance of a soft coating flowing in the right direction, produce one happy fluke-picture. And this is sufficient sometimes to establish a life-long reputation. He would have no such luck with oils. Engraver's ink does not move by itself.

Thus, after having carefully examined the numerous oil prints on the Photo-Club walls, one recognises three distinct classes of work. That of men who have tried to surprise the public by producing a print in oils that could be mistaken on close inspection for a platinotype, a carbon, or a bromide print; a purely technical success without much interest even from that particular point of view, for the number of such pictures shows that the feat is not a difficult one to achieve.

The second class comprises work similar to that of the first class in regard to the lack of medium quality, but showing on the part of the authors an evident and often successful preoccupation towards correcting false values and improving the general effect of their pictures. This is a step further. The third class, and I must confess that it is very much the smallest, shows *oil quality*. I mean to say that its peculiar charm, or its particular effects, are special to the oil process at its best, and could not be evolved through another medium. The authors of this kind of work have understood the personal advantages of the process, and have used one, several, or all of them, but always to the fullest extent. These pictures are sometimes imperfect from a technical point of view, when compared with the bromide style of oils. They are sometimes a bit risky in values, but, pictorially, they are distinctly pleasing; much more so to my taste than the correct but frigid prints of the preceding classes. Purists will certainly grudge them photographic quality, but we have become accustomed to this periodical grumbling. The same has been said about every new printing process since Daguerreotypes went out of fashion.

The English collection is composed of fifty pictures; three by Mr. Arbuthnot, one by Mr. Cocks, three by Dr. Evershed, six by Mr. Gear, five by Mr. Huson, two by Mr. Dudley Johnston, eight by Mr. Rawlins, one by Mr. Schilling, two by Mr. Basil Schön, three by Mr. Staddon, three by Miss Stevenson, two by Mr. Wickison, two by Miss Warburg, one by Mr. Warburg, and eight by Mr. Warner. I am told that it may be considered as representative of the élite of the British school. All these pictures are hung on one large panel, except those—in colour—by Mr. Warner, who has one smaller panel all to himself. The English monochrome work "*se tient bien*" (*holds itself well*), as we say in French. The general tone is subdued, and the technique (especially in Mr.

Gear's pictures) is very good; too good in some cases, for some authors show that perfection of technique has been their principal aim. One of Mr. Staddon's pictures, for example, absolutely perfect as to technique, and pleasing as a whole, does not appear to owe any of its qualities to the particular process that has been employed. It might be taken for an excellent and beautiful carbon print. The father of oils, Mr. Rawlins, shows eight interesting pictures treated in quite a different style from that which the French school has, more or less, adopted. The difference in tools and paper may account for this, independently of the personal factor. Mr. Dudley Johnston's large pictures, full of mystery and suggestion, count among the very best of the collection; but why has Mr. Johnston surrounded these delicate schemes in grey with heavy borders of dull black? Close framing, I believe, is only effective when the picture itself is stronger in tone and contrast than its surroundings, which is not the case with these delicate works. Mr. Gear seeks for effect, and gets it, though I cannot help quarrelling with the massiveness of some of his shadows (Burgos and Codova), and with the value of the background of "A Spanish Village." But the quality of his pictures is fine, and his sunlight effects sparkling. Other examples of strong, oily black and harmonious scales of values, will be found in "Marylebone Road" by Mr. Wickison, and the "Stadhuit Tower" by Mr. Lincoln Cocks. Mr. Arbuthnot's pictures are all of them very successful, the "Donkey Engine" especially, and Miss Stevenson has sent an excellent portrait of a gentleman. There is also a delicate Japanese effect by Miss Warburg; a portrait of a lady, who strongly resembles Queen Victoria, by Mr. Warburg; and some good work by Messrs. Basil Schön, Evershed, and Schilling.

Mr. Warner has courageously attacked the most difficult of the oil process, and his courage has been well rewarded. His eight prints in colour have attracted general attention. The tones chosen by Mr. Warner are subdued, and he has prevented any useless discussion about truth in colouring by frankly adopting a conventional rendering in two, and sometimes three colours without any attempt at oil painting by photograph. But I believe his pictures would be still more effective if the prints were well stretched and framed in the style of colour engravings.

Amongst the Belgian collection Dr. Cardyn stands pre-eminent with a very fine head of a man—one of the very best things in the room. He is undoubtedly a clever draughtsman, and perhaps because of this, he has not been able to withstand temptation to add here and there to his picture certain lines of pencil that do not add to the beauty of his work. Photograph prints, however altered by local development, will never show a black outline to a light tone against another light tone—it is distinctive of pencil or charcoal drawing—no manipulation inking an oil print will produce anything like it. But the study of a head is, nevertheless, quite remarkable. The rest of Dr. Cardyn's exhibit, though less striking, is far above average.

The French section counts such well known oil workers as Major Puyo, Mlle. Laguarde, M. Michan, Comte de Montge-

t, Viscomte de Singly, Messrs. Bidault, Billioque, Valke, ard, de Santeuil, etc. Mr. Potonnié is a new adept in the process, and his pictures claim attention at the outset. They are broad and daring in treatment, simple in subject and position, and they possess a quality which places them very high above the usual level.

This one process exhibition has had excellent results. It has proved that oil printing is not a fad of the moment, for when a process as young as this one is can produce five hundred

examples at a few weeks' notice, its vitality is made evident. Also as a lesson it has been more useful than the ordinary salons, because of the uniformity of the printing medium, which made conditions more equal for all exhibitors and allowed of a sounder criticism on the part of the public. It is to be hoped that the Royal Photographic Society will follow our lead, and devote its influence—and its spacious rooms—to bringing together the best examples of oil printing from England and the Continent.

ROBERT DEMACHY.

## THE MODERN NOTE IN THE DESIGN AND FITTING OF PHOTOGRAPHIC PREMISES.

### VI.

Under this title we continue, with the following article, a series of chapters by Mr. Drinkwater Butt, F.R.P.S., on the principles which should guide the photographer in the external design and decoration of his place of business, and in the arrangement and appropriate equipment of its various apartments. Photography being essentially an "artistic" business, taste and style need to be more in evidence than is necessary in businesses which are frankly and wholly commercial in their character. Therefore, while it is not possible to prescribe any plan which can be followed in particular cases, general rules can be laid down in such a way that a photographer can take advantage of them in giving his establishment, both outside and in, an air of distinction, which is bound to carry weight with his townspeople, and must turn out to his commercial advancement. Of course, a fortune may easily be squandered on such adornment of the studio, but in these articles Mr. Butt will confine himself to such schemes as a photographer in a moderate way of business need not consider beyond his means. Moreover, the articles will be of assistance in pointing out how particular materials may be used, even on the smallest scale, in improving or improving existing premises. The notes will conveniently be divided into four sections:—

Shop-front and Show-case.

The Reception-Room.

The Studio.

Planning complete Premises.

The last chapter will consist of a description of as complete a set of photographic premises as can be imagined—an establishment, in fact, which but few living photographers would feel justified in putting up. Yet the scheme in its various parts can be commended to the study of even the small photographer, on account of its detailing arrangements, which can be abstracted in pieces from their surroundings and utilised with advantage in businesses which are anything but magnificent in size.—EDS. "B. J."]

### Floor Coverings.

Floors of various sizes, and varying in effect from dark to light, however, very useful indeed, and may be seen included in all studio interior illustrations. Of the Oriental varieties the Persians are generally the best, as being small and broken in pattern and not sufficiently contrasty in colour to become inartistic in a photograph. Occasionally Japanese ones of similar character may be come across, and are, of course, very much cheaper, costing shillings as against the pounds it is necessary to pay to obtain really good Persian examples. The writer recently bought a quite nice Jap rug, to use in a painting studio, for less than half a sovereign. Some quiet, soft, and photographically good patterns are also produced in Wilton and Axminster, Messrs. Liberty recently supplying me with the former for the photographic studio of an earnest amateur worker in London, while I will probably shortly use more for a large business studio in Dublin. Large staring designs, such as are often met with in Brussels, must, of course, be avoided, as also a large quantity of red in the pattern of any make, as that colour will come startlingly black in the photograph, even if its reflection does not actually add to the necessary exposure of the

In this connection I recently came across a case in which I did not understand why a professional photographic pupil giving the very long exposures he reported and yet getting splendidly under-exposed negatives, until I visited his studio. I found a dull red paper on the walls and a brilliant red carpet on the floor, which together filled the place with red light, that was, of course, fatal to rapid work. On the carpet being taken up, the necessary exposure was reduced nearly fifty-five per cent., and later, with the paper removed, and

the whole place re-decorated in a lighter key, fifty per cent. less exposure yielded satisfactory negatives.

### How Four Walls were Made into a Studio.

To revert, however, to our illustrations, the two photographs of the "North Country Studio," Figs. 15 and 16, represent a place which the writer found as a mere barn, and converted, at but small expense, into the modest but not displeasing interior shown. As no structural alterations could be made, the very much too flat roof, and the insufficient windows for side light, had to remain as they were, and he made the best of in use, but the ugly iron girder which served as a purlin to the rafters was cased in, and a cornice formed round the room of similar wood moulding, while ornamental pilasters where required were formed partly from woodwork already in the possession of the proprietor. The "cosy corner" was constructed much in the same way, the frieze over the opening being part of an Adams mantel, and the "bulls'-eyes" in the glass doors of the corner cupboards being taken from an old house just then being pulled down in Hampshire. The studio was, as will be seen, quite a small one, but was liked by both operator and sitters as a useful and pleasant apartment to work in and visit.

As a further illustration to our subject we are also able, by the kind permission of Messrs. Speaight, to give a photograph of their studio in New Bond Street, in which their well-known and artistic child photographs are produced. As will be seen, this also is not a particularly large apartment, but it is furnished with all the knowledge and good taste which we have noted in a previous article as characterising their premises throughout. The pieces of furniture shown are all genuine antiques, and the scheme of decoration is noticeable for its quiet simplicity and restful effect. The studio is constructed for both day and

Fig. 15.—"A North Country Studio."

Fig. 16.—"A North Country Studio."

electric light use, the installation of the latter illuminant consisting of eight large arc lamps of ten thousand candle power each, the light from which, though used by reflection only, is quite sufficient for the very short exposures naturally required by the exigencies of their special and difficult business. The

backgrounds used are all on stretching frames, which slide one behind the other in a set of grooves at the end of the studio so that any one required may be easily brought into position behind the space reserved for the child sitters, with whom Messrs. Speaight are so very successful.

### A Design for a Complete Studio.

Our final illustration is a sketch by the author, for the arrangement and furnishing of the studio which forms part of the complete photographic premises, the general planning of which will be discussed in the next and final article of this series. It

Fig. 17.—A Studio at Messrs. Spaight's, Limited.

rather exceptionally large apartment, being somewhat over twenty feet in size, with a total height of about four feet. It is designed, as will be seen, on the single slant principle, which, where sufficient height can be obtained, is certainly the best form for the glazing of a photographic studio, as a weather-

light tee iron, and so obstruct the illumination far less than the necessarily stout wall plate of the ordinary span or lean-to construction. In the latter, indeed, the plate has often to be made so heavy that it cuts the light into two, and consequently gives double high-lights in the eyes of the sitter, which spoil the expression if left, or cause much unnecessary work for the retouchers and spotters if taken out on the negative or prints. The pitch of the roof is sixty degrees, so that there are actually only one or two days at midsummer, when the sun at its highest noon altitude can look over the ridge into the northward facing apartment.

The roof, apart from the glazing, is of slate at the sides, with a zinc flat at the top, and is carried on the two steel principals shown, the tie rods of which, it may be noted, are kept at nine feet from the floor level, to allow of ordinary sized backgrounds on stretchers or stands being moved easily beneath them.

The glazing is carried to within four feet of each end of the studio, but in the drawing the blinds are shown partly covering it at different heights to make their positions and use more clearly intelligible. They are, of course, fixed upon spring rollers at top and bottom. For artificial lighting eight large electric arc lamps are shown suspended from the roof, the light from which could be used by reflection in the same manner as in the studio of Messrs. Speaight already referred to.

The semi-circular recess at the east end of the studio has also already been described. The window at the same end, which opens on to a well top-lighted landing, can, of course, be curtained off, or used to modify the lighting, or as a background or accessory in itself, which latter use might also at times be

Fig. 18.

roof is thus most easily and surely obtained by the use of Simplex, or other patent system of glazing without putty; it is also easily cleaned, does not retain fallen snow upon it, and is a simple form for which to arrange the blinds, one set pulling down, and the other up to the purlin, which, owing to the steep pitch of the sash bars, can be made of

made of the mantel and its adjoining seats. The doors to left and right lead respectively to the dark room and to the stairs and lift.

The general scheme of decoration would be cream or ivory white for the ceilings and woodwork, with a warm gray ingrain paper for the walls; the floor being of parquet in two tints, or

of inlaid linoleum of similar pattern. The furniture shown embraces both antique and modern examples, as already referred to, and includes a cabinet which would be found very useful for containing toys, etc., which might repose unseen therein until wanted at the critical moment for the wonder and delight of child sitters. A good movable multiple background stand

and perhaps one or two well-designed architectural accessories are about all that is required to complete the furnishing, and these may be imagined as being at the end of the room not shown in the drawing.

DRINKWATER BUTT, F.R.P.S.  
(To be continued.)

## CONVERSATIONS ON COPYRIGHT.

[COPYRIGHT.—The sole and exclusive right of copying, engraving, reproducing, and multiplying any photograph and the negative thereof by any means and of any size [Extract from the Copyright (Works of Art) Act (1862)]. The following article concludes the series of chapters on the law of copyright, in which our aim has been to place the chief points in copyright law in a way in which they can be grasped more easily than in a set treatise. The subject has been divided into five sections, viz.:—I. Ownership of copyright. II. Registration of copyright. III. Sale or part sale of copyright. IV. Infringement of Copyright. V. The present and last conversation—foreign and international copyright.]

### V.—FOREIGN AND INTERNATIONAL COPYRIGHT.

Q.: I take it from our subject this week that copyright is obtainable in other countries as it is in England?

A.: Certainly it can be obtained; but the conditions are different in almost every country. Different formalities are necessary, and the degree of protection is different.

Q.: Just so; but this is a matter which interests only those in these countries. The point on which I should like some information is how the Englishman secures rights abroad in photographic works which he makes at home, or when travelling—at any rate, which he registers in London.

A.: That can be easily explained. The only countries in which copyright can be sustained are those forming what is known as the "Copyright Union." All these subscribe to the "Berne Convention," under which a mutual exchange of copyright protection takes place.

Q.: Great Britain is a member of the Union, I suppose?

A.: Certainly; and so are the chief civilised countries, the chief exception being the United States of America.

Q.: Can you say on what terms this mutual copyright protection is arranged?

A.: The general arrangement is as follows:—A photographer here who complies with the usual formalities, i.e., registers the copyright, obtains in the other countries of the Union the degree of protection which is granted to each on compliance with the respective formalities of each country. In other words, you do what is necessary here and you get in Germany the same degree of protection which a German secures by complying with the formalities of his own country.

Q.: And *vice versa*, I suppose, a German by complying with the formalities in his country thereby obtains protection in England to the same degree that we do here.

A.: That is so; the Convention works equally all the way round.

Q.: Thus, I as a photographer do not require to know the

formalities required in the foreign countries, but only those in my own. But I do require to know something of the protection granted under Copyright Law by the various countries.

A.: Yes, that is the point. But the chief difference is in the duration of the copyright.

Q.: This varies in the different countries?

A.: Yes; in Germany it lasts for five years from the time of the first publication of the prints or from the making of the negatives; in Belgium and Denmark it lasts for five years after the death of the author; in Spain for eight years after the death of the author; and in Sweden for five years after publication.

Q.: I am told that the conditions in France are somewhat peculiar.

A.: They are. It seems that in France copyright protection is obtained only by photographs which are judged to have artistic merit. The judges decide whether a photograph is a work of art or not. I should also tell you that in France, by an Act of 1902, copyright can be obtained in designs of buildings, and an architect can prevent a photograph being taken of a private building for purposes of profit.

Q.: These differences may be taken, perhaps, as the chief one in connection with foreign copyright.

A.: At any rate, they state the general principle of foreign copyright; but the subject abounds in intricacies, and, so far as has not been cleared to any extent by cases in the courts in which photographs were concerned.

Q.: As regards the Colonies, are the conditions the same as in England?

A.: They are supposed to be; but the administration of the Copyright Act appears to be very lax, and where time permits it is better in many cases to send the prints to London for registration.

(Conclusion.)

MEXICAN OPENINGS FOR CINEMATOGRAPHS.—In an American Consular report which has just reached London, the question of openings for cinematographs in Mexico is touched upon. The Consul states that he is frequently addressed for information concerning cinematograph shows in Mexico city, and the prospects open to Americans in that line. The invariable answer is that Mexico City is no exception in regard to the general favour which such exhibitions enjoy in the Spanish-American capitals. There are three or four well-known shows of this kind which are patronised by the best of Mexican society. The charge is 25 centavos (approximately 6d.) for admittance, including a seat, without distinction of location. Some private families, on such occasions as birthdays and other family celebrations, will hire the cinematograph and have it brought to their homes for an afternoon or evening performance. Apart from the well-

patronised cinematograph establishments, there are other small ones dotted about the city. One or two cinematographs are maintained for advertising purposes upon the public streets, and the alternate interesting views with paid advertisements. One large cigarette-making establishment in the city has a well-conducted cinematograph theatre, to which admission is obtained only by the presentation of a given number of coupons which accompany their cigarettes. All these cinematographs are of foreign make. The views used are almost exclusively of French make, and they depict scenes in Continental European life, which are apparently the only ones which appeal to the public. In conclusion, the Consul says: "I do not think there is any field for an American cinematograph in the city, nor would American views touch a responsive chord in the average Mexico City audience."

## THE HINTON MEMORIAL FUND.

On the announcement of this fund, in our issue of April 10, a large number of donations, we are glad to say, have reached the Treasurer of the Fund, Mr. Reginald Craigie, 52, Long Acre, London, W.C. The "Amateur Photographer" has acknowledged their receipt in its last numbers, but we may now publish a complete list of the donors up to Tuesday last, April 28.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between April 13 to 18:—

PRINTING.—No. 8,123. Photographic printing machine. Cyril Mantegani, 35, Stockton Street, Manchester.

TELECTROPHOTOGRAPHY.—No. 8,135. Telectrophotographic apparatus. Pascal Berjonneau, 6, Great Winchester Street, London.

CAMERAS.—No. 8,201. Device for fixing objects on photographic cameras. Karl Lenck, 40, Chancery Lane, London.

CAMERA STANDS.—No. 8,314. Improvements in and relating to camera stands. Wilfred Asa Fessenden, 40, Chancery Lane, London.

SCREENS.—No. 8,368. Solid inactinic screen. Xavier Jeannet and Emile Mauvillan, 20, High Holborn, London.

CAMERAS.—No. 8,443. Improvements in photographic camera apparatus. Alfred George Brookes, 55, Chancery Lane, London, for Ammi Vining Young, Germany.

CINEMATOPHOTOGRAPHS.—No. 8,496. Apparatus for synchronising talking machines with cinematographs. Alfred Duskes, 116, High Holborn, London.

FIREPROOF FILM.—No. 8,542. Uninflamable film for cinematographs and a process of manufacture of same. Gaston Chandon de Briailles, 1, Queen Victoria Street, London.

PRINTING FRAME.—No. 8,621. Improved photographic printing frame. David Ralston and John Steel Ralston, 65, Chancery Lane, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

PRINT TRIMMERS.—No. 14,760, 1907. The invention relates to the type of trimmer comprising a hinged table having a cutting edge mounted along (and a short distance above) one edge, the article to be cut being placed on this table and beneath the cutting strip. A knife with inclined edge is situated at right angles to the plane of the table, the edge of this knife bearing against the cutting edge carried by the table with a shearing action as the table is depressed or turned about its hinge. The table is returned to its initial position ready for another cut to be made by the action of a spring. The knife is hinged so that it can fold down underneath the table when not in use.

The disadvantage of this construction is that the edge of the print or other article which it is desired to cut has to be hidden beneath the cutting strip carried on the table, and thus difficulty is experienced in spite of the graduated scale with which such cutters are provided in regulating the amount that is to be

cut off, and the position of this cut with relation to any particular mark or object appearing on the face of the paper.

According to this invention the cutting strip, in place of being mounted actually on the edge of the table, is turned round so that its cutting edge faces the edge of the table, the cutting strip lying beyond this edge. Between the edge of this cutting strip and the edge of the table is a space in which works the knife blade, which, of course, instead of being pressed against the edge of the table, is pressed away from it against the edge of the

Fig. 1.

cutting strip. The paper can with this arrangement be laid on the table with the portion which is to be cut off beneath the cutting strip, and the paper can be nicely adjusted so that the edge of the cutting strip is placed exactly as required, the objects or marks on the paper being in full view the whole time.

The device may be made to fold into a small space in a similar way to the known form of cutter on which it is an improvement. The knife blade, however, in the improved construction folds upwards, and the upward movement of the table, which takes place under the influence of the spring beneath it, is checked by a pivoted slotted link engaging with a pin and mounted on one or both sides of the table, the arrangement of the links being such that the table is free to turn about its hinges when cutting is in process, but the links will recede within the framing when the device is folded up and secured by some convenient form of catch.

A cord or chain may be employed instead of the restraining links or other like device as found convenient.

Fig. 2.

The angle of the cutting blade may be arranged so that the cut takes place either from right to left, or *vice versa*, as desired.

The cutting strip may be mounted in various ways, but is preferably carried on metal L-shaped brackets attached to the front edge of the table, these brackets being, of course, clear of the ends of the knife. Where it is desired to have the full length of the cutting strip available, this strip may be carried on arms or brackets extending from or mounted on the sides of the table, the framing within which the table shuts down being shaped accordingly so as to clear these arms.

In the figures the table, A, is connected to a suitable base or frame, B, by means of hinges, A<sup>1</sup>, and is pressed upwards by means of springs, B<sup>1</sup>, mounted on the base, B, the upward movement of the table being limited by stops, A<sup>2</sup> and B<sup>2</sup>, carried by the table and base respectively. Mounted a short distance beyond but parallel to and carried by the upper edge of the table A is a cutting strip, C, the cutting edge of which faces the edge of the table, a longitudinal slot being thus formed between the edge of the table and that of the cutting strip, C. The cutting strip, C, may be connected to the table in any convenient manner, but is

preferably carried by L-shaped brackets, such as C<sup>1</sup>, secured to the side edges of the table by screws or the like, the cutting strip being in turn attached to the brackets, C<sup>1</sup>, by screws, so that it can be readily removed when it is to be sharpened.

Mounted on the base B is a knife D, the edge of which is inclined at an angle so that—in the construction illustrated—the cut takes place from left to right. The upper extremity of the inclined knife, D, projects a short distance through the left-hand end of the longitudinal slot formed by the edge of the cutting strip, C, and that of the table, A. The knife, D, is conveniently hinged to the base, and is provided with springs, such as D<sup>1</sup>, which maintain it in contact with the cutting edge of the strip. The edge of the table from which cutting commences is conveniently provided with a rule or gauge, such as E, which also serves as a guide for the paper which is being cut.

In using the apparatus the print is placed upon the table, so that the edge which it is desired to trim lies beneath the cutting strip, C, the cutting edge of the latter coinciding with the line along which it is desired to cut. The table is now depressed in opposition to the action of the springs, B<sup>1</sup>, and the print is trimmed, the cut taking place from left to right as the table is depressed, and the edge of the knife rises in the slot between the edge of the table and that of the cutting strip, C.

When the apparatus is not in use it may be folded flat, and this end the stop, A<sup>2</sup>, can be moved out of contact with the stop, B<sup>2</sup>, on the base. The table, A, is thus free to rise under the action of the springs, B<sup>1</sup>, and in consequence rises clear of the upper extremity of the knife, D, enabling the latter to be folded outwards into the position shown in Fig. 2. The table is then depressed, the upright portions of the springs, D<sup>1</sup>, projecting

Fig. 3.

through the slot formed by the edge of the table and the cutting strip, C, and the whole apparatus is retained in its inoperative position by the stop, A<sup>2</sup>, being moved into its initial position, so that its outer extremity engages the underside of one of the transverse pieces, B<sup>3</sup>, of the base. Joseph Thacher Clarke, Gay Corner, Harrow, Middlesex.

**SELF-PORTRAIT SHUTTER.**—No. 8,175. 1907. The invention aims to provide a means whereby the shutter of a photographic camera may be released or operated to give an exposure in a manner such that the operator may include himself in the picture without assistance and without the aid of a pneumatic tube or other direct connection with the camera. The arrangement has been more especially devised for employment with portable cameras, but it may be applied to other cameras.

A spring is provided for connection to the shutter-releasing operating lever, this spring being adapted to actuate the lever device to release or operate the shutter. In some types of camera the existing shutter-operating spring will serve the purpose. Means are provided whereby the releasing or operating lever can be held against the action of the spring for a sufficient or desired time and then freed, whereupon the spring at once actuates the lever device and the shutter is released or operated. These means consist of a thread or combustible connection adapted to be attached to the releasing or operating lever or device and to a suitable point of the camera. The thread or the like may be attached to this point by means of a spring, to compensate for any variations in the length of the thread and ensure the same remains taut and holding the releasing or operating device against the action of its spring. The thread may be provided with loops at its ends, so that it can be readily attached to the releasing lever or operating device, compensating spring, or other part. The thread or the like is attached a strip of slow burning material such as touch-paper.

In the drawing the invention is shown as applied to a well-known type of camera, wherein the shutter is usually released by a lever actuated by a piston *b*, which is operated by a pneumatic release. To a suitable part of the camera above the releasing lever *a* is connected a coiled spring *a'*, which can be hooked when desired to a hook *c* on the lever *a*. The latter has another hook *d* for the reception of a thread *e*, which is also passed on to the hooked upper end of another coiled spring *f* attached to the camera below the releasing lever *a*, and serving to keep the thread taut. To the thread is attached a length of touch-paper or fuse *g*.

When the shutter being set, the thread is attached or hooked in place as to hold the releasing lever *a*, and the operating spring *a'* when hooked to the lever *a*. The touch-paper being then ignited burns slowly until it reaches the thread, which at once breaks and frees the lever *a*, so that the shutter is operated and gives the exposure. By employing strips of touch-paper of suitable lengths the time elapsing before the release of the shutter can be varied as desired. The operator can carry with him a supply of threads and attached strips of slow burning material, and can readily replace them in place as occasion requires. Alfred Greeff, 45, Kerstrasse, Weimar, Germany, and Robert William Creeff, 20, Cheap, London.

The following complete specification is open to public inspection under the Patents Act, 1901:—  
No. 7,897. Animated stereoscopy by the employment of a single film with small images. Dupuis.

### New Trade Names.

TRADE MARK.—No. 301,230. Cinematograph films bearing taken-up photographs. Alfred West, 7, Villiers Road, Southsea, Hants, manufacturer. March 11, 1908.

## Analecta.

Extracts from our English weekly and monthly contemporaries.

### Crescent Moon Photographs.

In a suitable room was selected (writes Mr. William A. Everard in the *Photographic Monthly*), one with a small fanlight that could be opened, the glass being covered with brown paper. The moon was then set out on fine canvas by the simple expedient of laying it flat on the floor, and marking the crescent with a blue pencil fastened by a string to a small nail, driven slightly into the floor, and used as the pivot; first marking with full length of string, then with about five inches shorter. The canvas crescent was then cut out with a pair of scissors, and afterwards whitewashed. Then

all the black cloth one could get was borrowed to make the background and cover the seats. One strip was tacked along the whole front to hide the dress of any one behind. Stars were cut out of white paper and fastened by pins put straight through the centre. The crescent was fastened to strips of wood with one large sheet, which was fastened to two strong boxes forming the seats.

### Measuring Photographic Chemicals.

Drops have occasionally to be measured in photographic practice (writes Dr. Chas. W. Budden in *"Focus"*). The bottle should be lightly grasped in the right hand by all the fingers, except the index one, and held in a vertical position with the bottom downwards, till the stopper is partially lifted out with the fingers of the left hand, and it is then held there by the right index finger, which presses it downward as the bottle is gently tilted to allow the liquid to run out. Before permitting the drops to fall into any quantity of developer or other solution, a few should be allowed to drop on the floor or on to a dish till one is satisfied that he has perfect control over the regularity with which the drops issue, otherwise they might come out with a rush and too much be added.

## New Books.

**THE CARBON PROCESS.**—Although it may be argued that there is practically nothing new to say about carbon work, yet a concise résumé of the general principles and working instructions of the process by a competent authority should be of value both to the novice and to the experienced worker. With this object, and also with a desire to further increase the use of the process, the Autotype Company have issued a booklet, written by Mr. A. C. Braham, F.R.P.S., head of the firm's technical staff at West Ealing, which deals with the process from start to finish in a brief and lucid manner, leading the beginner, step by step, along the lines of successful working. Starting with the general principles of the process and particulars of the necessary materials and apparatus, the worker is conducted by easy stages through the operations of sensitising, printing, developing, mounting, etc., in such a manner that failure should be almost impossible. The chapter on sensitising contains a lengthy reference to the Autotype spirit sensitiser, an introduction which has made it possible to successfully work the process in hot climates, notably in India, where hitherto its use had only been practicable for a short time in cool weather or at high altitudes. Although written primarily for the novice in carbon work the booklet also contains hints and wrinkles from the author's 25 years' experience which should be of considerable value to the regular user. The price of the booklet is 6d., and may be obtained from the Autotype Co., 74, New Oxford Street, London, W.

**THE HORSLEY HINTON PORTFOLIO.**—The large number of photographers who have known and appreciated Mr. Hinton's pictorial work will doubtless be glad of the opportunity of possessing reproductions of some of his best-known pictures. To this end the proprietors of *"The Amateur Photographer"* have issued a portfolio containing photogravures of the five—namely *"Melton Meadows," "Fleeting and Far," "Recessional," "Weeds and Rushes,"* and *"Niagara"*—which have in the past received most general public appreciation. The reproductions are each on an imperial quarto sheet of antique paper, bearing a facsimile of Mr. Hinton's signature, and are inserted loose in a portfolio, accompanied by a brief notice of their producer's career and a criticism of the pictures themselves. Applications for the portfolio, which will be sent post free to any address in the United Kingdom for the sum of 6s. net, should be addressed to the office of *"The Amateur Photographer,"* 52, Long Acre, London, W.C.

**THE SUBURBAN AND PROVINCIAL DEVELOPMENT ASSOCIATION**, of 29, John Street, Bedford Row, W.C., have just issued a further instalment of their illustrated booklets, the purpose of which is to bring the various districts dealt with before the notice of those who are contemplating changing their place of abode. These latest additions deal with the districts of Surbiton, Richmond, Beckenham, and Kingston-on-Thames, and may be obtained, post free, on application to the respective Town Clerks.

## New Materials, &c.

"Luxepia" Printing Paper. Made by the Luxia Co., South Hill Works, Hampstead, London, N.W.

We have in this material a development printing paper giving directly a sepia print of very fine tone indeed. The treatment of the paper is practically that of the ordinary gaslight paper, except that development lasts somewhat longer than is usual in a paper of this class. It should be completed in about 75 seconds for the best results. As regards rapidity, the makers state that about 2 seconds exposure to diffused daylight is about correct for an average negative, an estimate which we think may lead to under-exposure of the paper, for, in our own trials, in the afternoon light of a day or two ago, we found it necessary to give at least 20 seconds exposure to a negative which was as thin as would give a good P.O.P. print; in fact, a negative which was distinctly thinner than one to which the description "average" may be applied.

The developing solution of the "Luxia" paper is made up as follows:—

Water .....	18 fluid ounces.
Potash metabisulphite .....	25 grains.
Soda phosphate .....	450 grains.
Potash citrate .....	180 grains.
Hydroquinone .....	50 grains.

from which it will be seen that it differs from the developer ordinarily used for bromide or gaslight papers in containing no alkali, a fact which will perhaps give a hint to those who have read our columns carefully during the past few months as to the means employed for securing the sepia tone. Fixation is done in the ordinary way in a hypo bath containing 3 ozs. per pint, with also a few grains of potassium metabisulphite. For both contact and enlarging work the "Luxia" paper is certainly a notable addition to the facilities at the disposal of the photographer. The tone is quite distinct from the effect usually obtained by any of the sulphide methods, possessing greater luminosity in the shadows and being of a more true and agreeable sepia colour than that which is frequently the result of sepia toning. The paper is manufactured in glossy and matt varieties, both of which are marketed in shilling packets containing twenty-four quarter-plate pieces or a greater or less number of smaller or larger sizes. It is also issued in official postcard size at a price of sixteen cards per shilling packet, or 8s. per gross.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, MAY 1.

United Stereoscopic Society. "A Stereoscopic Mystery." A. J. Snow.  
West London Photographic Society. Arranging Summer Programme.

SATURDAY, MAY 2.

North Middlesex Photographic Society. Record Outing to Hendon.  
Liverpool Amateur Photographic Association. Excursion to Gosford and Marford.  
Chelsea and District Photographic Society. Excursion to Burnham Beeches.

MONDAY, MAY 4.

Harrow District Photographic and Scientific Society. "Fleet Street." E. Young, B.Sc.  
Bowes Park and District Photographic Society. "Frame Making." Hy. C. Bird.  
Kidderminster and District Photographic Society. Development. Kodak, Ltd.

TUESDAY, MAY 5.

Royal Photographic Society. "The Half-Tone Process." Leslie Clift.  
Hackney Photographic Society. "Walks with a Camera in London." A. H. Blake, M.A.  
Handsworth Photographic Society. Council Meeting.

WEDNESDAY, MAY 6.

Edinburgh Photographic Society. "Thoughts Suggested by the Rembrandt Tercentenary." W. D. Mackay, R.S.A.  
Croydon Camera Club. Exhibition of Prints taken on the Good Friday Excursion.  
Central Technical College Photographic Society. "Sports and Pastimes with the Geertz-Anschutz Folding Camera."  
North Middlesex Photographic Society. Lantern Slide and General Print Competitions.

THURSDAY, MAY 7.

Tunbridge Wells Amateur Photographic Association. Photography Prize Slides.  
North London Photographic Society. "Oil Painting." Dr. A. R. F. Evershed.  
L.C.C. School of Photo-Engraving and Lithography. "Some Particular Applications of Process Engraving to Advertising." Frank Colebrook.  
Midlothian Photographic Association. "In Brittany with a Camera." Ed. G. Gallely.  
Southend-on-Sea Photographic Society. Amateur Photographer and Focus Prize Slides.  
Handsworth Photographic Society. "Enlarged Negatives by Reversal." Arthur J. Powell.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, April 28. A demonstration of the Carbo-graph process was given by Mr. H. Jackson, of the Rotary Photo-graphic Company. The demonstrator explained the principle of the process, and then proceeded to give an actual demonstration of the production of a carbon print by the exposure of the carbograph paper. The demonstration was witnessed with considerable interest. Previous to the demonstration Mr. Oliver Dawson showed and explained an apparatus for demonstrating the path of rays of light, the construction of which led to some little discussion.

SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.—The first annual general meeting of this flourishing Society was held on Wednesday evening April 22, at Plough Hall, Lewisham, with Mr. P. C. Cornford in the chair. A very satisfactory report was presented by the hon. secretary and treasurer. During the year the society had increased from 112 to 178 members. There has been one death, and recently nine resignations, leaving 168 on the list. Thirteen subscriptions were in arrear, but after paying all current expenses the treasurer has £2 12s. 7d. in hand. As the preliminary expenses (£5 14s. 6d.) incurred by the organising committee before the society was launched will not recur, and as certain other items will be less in future than in the past, the financial outlook is, on the whole, favourable. The society, before the close of its first year, was numerically the largest in England, with the exception of Hull, Manchester, Leeds, and Liverpool. It had even outgrown its older neighbour, the South London P.S., which could only show a list of 166 members. Including excursions, fifty meetings had been held during the year. With the 5s. subscription, therefore, the cost per member per meeting worked out at less than 14d., and at this rate no one could complain that he did not receive full value for his money. It now remained for the members to make the society the biggest and most efficient, as well as the most economical society in the kingdom. Mr. F. J. Mortimer was re-elected president, Mr. F. Nixon hon. sec. and treasurer, Mr. F. N. Palmer portfolio secretary. Mr. A. E. Bache and Mr. F. J. Wills were appointed assistant secretaries, and Mr. P. H. Dannatt as hon. lanternist. Vice-presidents and a strong committee were also elected.

## Commercial & Legal Intelligence.

ALLEGED PHOTOGRAPHIC FRAUDS.—Before Sheriff Begg, at Aberdeen, last week, Charles Gibb (25), labourer, 17, Claremont Street, was examined in connection with eleven charges of fraud and theft of it. It is alleged that accused committed the frauds by a scheme of supplying enlarged photographs and picture frames to house-holders in Aberdeen. Gibb, who was represented by Mr. D. M. Donald, solicitor, emitted a declaration, and was committed for trial.

BANKRUPTCY.—Richard Berwick Hope, photographer, of 154, Portdown Road, Paddington, lately residing at 11, Iddesleigh Mansion, Victoria Street, S.W., and lately carrying on business at 171, New Bond Street, has been adjudicated bankrupt.

ENLARGEMENT FRAUDS.—At the Leicester County Police Court, last week, George Percival Marston, a canvasser, living at "The Rookery," Thurmaston, was charged with obtaining by false pretences, on March 30, 3s. 6d., the money of Annie Norman. Mr. J. T. Hincks appeared for the defence.

Mrs. Norman, the wife of John Arthur Norman, said on February 29 a young man (the prisoner) and a young lady knocked at her door. The young lady asked witness for a small portrait to enlarge. Witness had not one, but said her friend, Mrs. Lucas, of Cross Street, had one. They brought several "bits of frames" for her to look at, and witness picked one at 7s. 6d. The lady said the young gentleman would call for the money. The paper (produced) was given to her. It read:

"Free.—The Great Central Portrait Company's special offer. enlargements given free as an advertisement (life size, 20 x 16), be framed by us from 7s. 6d. Photos carefully returned. District Office: Wharf Street, Leicester. Agent ——. Date ——."

She expected she was dealing with a firm with a district office Wharf Street. She went on the Saturday following to Wharf Street but failed to find the office. On her return her daughter showed her a card, on which was entered the payment of 1s. On March 9,

23 she gave prisoner separate shillings in payment, but on the date she asked him to bring the enlargement. He promised to go on March 30, but failed, saying it was not quite dry, and that should come up about three o'clock on the following Tuesday. He left her the office was opposite the "Empire," and "seemed so right" that she parted with 3s. 6d. On the following Monday saw prisoner in Oadby, and informed him that she had again failed to find the office. He offered to take her to find the place, but failed to keep his appointment.

C. Barratt, stationed at Oadby, said on April 15, about 8 p.m., went to defendant's house at Thurmaston, in company with Superintendent Bowley, and told him he had two warrants for his arrest. Witness cautioned him, and prisoner said he had no photographs in the house, as they had all gone to London. On approaching the board prisoner told him it only contained his child's playthings, and witness found two boxes of photographs, one of which was Mrs. Man's. There were three or four hundred tickets, and a large quantity of collecting cards. Prisoner was brought to Leicester and fined.

Further charge of obtaining by false pretences from Mary Ann, 1s. 6d., between March 9 and March 23, was then proceeded to.

Prosecutrix, the wife of John Dixie Wood, a shoe-hand, of Oadby, on March 6 prisoner called upon her and asked her for a photograph to enlarge free, "simply for advertisement." She gave him a photograph on the understanding that he would bring it back again day or two. He gave her a receipt for the photograph, and said the office was facing the "Empire," in Wharf Street. He called next day for the 1s., after which, he said, he would give her the enlargement. After she had paid the shilling he did not bring the portrait, as he said he would like her to pay a little more. On March 16 he brought her original photograph back, and stated that enlargement looked all right. The following week she paid him but he said nothing about the portrait, and a week later she failed to pay him any more money until he brought the portrait. He saw nothing further of prisoner, and had not received the enlargement.

Prisoner pleaded not guilty to both charges.

Mr. Hincks stated that prisoner had entered his payments in a book. He (Mr. Hincks) produced receipts for enlargements from several people who had been contented. There was no doubt that there were no such business premises in Wharf Street. Prisoner had been entirely to his lady companion in the business, and they were in communication with a London firm who did the enlargements. Prisoner, however, took the whole responsibility on his head.

Superintendent Bowley stated that since the affair had received publicity he had been simply inundated by people applying for their photographs, who on giving them up had heard nothing further.

Mr. Hincks: 102, I think. He has sent his photographs to the same company.

Superintendent Bowley stated that the photographs found numbered 116, and of these twenty had been claimed. Sums varying from 1d. to 8s. had been paid, and in several cases nothing further had been heard. The cost of the enlargements was about 7½d., and it was stated that prisoner had told him while coming from Thurmaston cost was 3s. 1½d.

Mr. Hincks: With travelling expenses, etc., it just comes to a shilling wage.

The Chairman said both cases were proved, and prisoner would be convicted. He appeared to have gone to poor people's houses, and asked them to give him a photograph to enlarge; they paid him for the enlargement, and he had no intention of fulfilling the bargain. Bench looked upon it as a very serious offence, and the least that could be done, in each case, was to send him to prison for two months and to do hard labour.

#### NEW COMPANIES.

WATSON AND SONS, LTD.—Registered April 9. Capital £30,000, 100 preference and 24,750 ordinary shares of £1 each, and 5,000 preference shares of 1s. each. Objects: To take over the business of manufacturers of optical, photographic, and other scientific instruments, carried on by C. H. Watson and F. W. W. Baker, at 313, High Holborn, as W. Watson and Son. No initial public issue. Registered office, 313, High Holborn, W.C.

## Correspondence.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

OLD MASTERS IN GERMANY.

To the Editors.

Gentlemen,—In a footnote attached to the notice sent you by a correspondent on the Exhibition of Old Masters in Germany, you have already repudiated the statement that anybody photographing pictures by old masters can restrain the issue of reproductions of the paintings in England.

As a good deal of the statement in the article is altogether wrong, we ask you to allow us to mention that, first of all, the Royal Academy of Arts, on whose behalf the publication was primarily to be issued, made a clear application to all the owners of the pictures that were lent to the exhibition, asking them for permission to reproduce the pictures, firstly, in a small catalogue which was on sale during the exhibition, and, secondly, in the edition de luxe to be published by our Berlin house. To this request all the owners have most courteously given their assent, with the exception of three, whose pictures, as a matter of course, will not be included in the work.

This work is strictly limited to five hundred copies, of which a considerable number is to be presented to distinguished persons interested in the exhibition, like his Majesty the King, the German Emperor, and the various owners who, by lending their pictures, have made the great success of the exhibition possible. It need hardly be added that, of course, none of the owners of the pictures included in this work lose thereby a tittle of their rights.—We are, dear Sirs, yours faithfully,

THE BERLIN PHOTOGRAPHIC COMPANY.

133, New Bond Street, London, W.

#### THE FERRICYANIDE-BROMIDE-HYPO REDUCER.

To the Editors.

Gentlemen,—The very interesting results obtained by Mr. Welborne Piper, and published in to-day's issue of the "Journal," on the effect of introducing a bromide salt into the well-known Farmer's reducer, induce me to lay before you the results of some experiments of my own with this reducer, although pressure of other work has hitherto prevented me from exhausting the questions they raise.

I found that, as usual, this reducer tends to "cut" in the shadows, but the extent to which this occurs undoubtedly varies appreciably. Using strips cut from a stepped (H. and D.) negative, I found that occasionally the action starts vigorously enough, and eats away the lighter densities and partly reduces the heavier ones, and then appears to cease, and cannot be made to proceed further, either by addition of more ferricyanide or even a fresh mixture of ferricyanide and hypo altogether.

I tried a good many experiments to determine the conditions under which this peculiar effect occurs, such as working with solutions of different strengths and proportions, using freshly prepared and also relatively old solutions, mixed from a quarter to three-quarters of an hour before use, working in artificial light, and also in strong daylight, but without result. The behaviour is somewhat erratic, and at present I can only suggest that the presence of traces of silver salts and hypo in the negatives employed, which were old strips washed for times varying from a quarter of an hour to one or two hours in ordinary tap-water, sometimes in changes and sometimes in running water, may be the cause.

The first interesting point is that, when using ordinary Farmer's reducer, this phenomenon occurs fairly often in a slight degree, the high densities being reduced less in proportion than are the low densities, and I can state positively that now and then a residue, still of great opacity, remains, which is no longer attacked by Farmer's reducer, either old or freshly prepared.

The second point is that this effect is never met with, in my experience, if the ferricyanide be applied first, followed, after a short washing, by the hypo bath. The result exactly resembles that described by Mr. Welborne Piper, the details are not cut away, and the high-lights are fully reduced. The difference in gradation between two negatives, one reduced with the combined and the other with the separate solutions, is well marked.

I am unable to agree with Mr. Welborne Piper's statement that ferricyanide alone attacks silver slowly, as I have always found it possible to effect a very strong reduction in a few minutes.

These observations and the known oxidising action of ferricyanides on hypo, leading to the precipitation of sulphur in a few hours, incline me to the opinion that a certain amount of deposition of silver sulphide or a partial conversion of silver to the sulphide goes on in the higher densities when Farmer's reducer is acting on a negative.

If Mr. Piper or any other gentleman can spare the time to elucidate this matter I feel sure photographers generally would be interested, and I personally should feel very grateful to him, as I fear it will not be possible for me to touch the matter again for some time.—

Yours faithfully,

F. F. RENWICK.

Norland House, Avenue Road, Brentwood.

April 24, 1908.

To the Editors.

Gentlemen,—Mr. Piper's note in your last issue with reference to the modification of Farmer's reducer by the addition of potassium bromide is most interesting. I can fully bear out his statement of its action, speed of working, and more general reduction of the silver image. The method must have occurred to many of those bromide workers using the sodium sulphide toning process. Other bodies than potassium bromide can accelerate the bleaching action of the simple solution of ferricyanide, which is fearfully slow used by itself. Two or three drops of a strong solution of ammonia at once starts an energetic action. Here we have another hint for a possible modification of Farmer's reducer. I have fully proved for some time past that the addition of ammonia to the reducer accelerates its action, prevents the tendency to yellow stain, and modifies the character of the reduction, which, instead of increasing contrast, seems to slightly reduce it, but not to a pronounced extent.

A modification of the reducer by adding both ammonia and potassium bromide, taking advantage of both accelerating agents, has rendered me excellent service for some two years past. Which addition is the more active I never took the trouble to determine, but used both from some hazy notion that if the one failed the other would carry the action on.—Yours faithfully,

A. EDWARDS.

The Laboratory, Corporation Gas Dept., Leeds.

#### ENLARGING EXPOSURES AND LANTERN CONSTRUCTION.

To the Editors.

Gentlemen,—Considering the novelty of the unorthodox views expressed in my lecture on "Exposures in Enlarging," the necessarily condensed form of the lecture itself, and the still more abbreviated character of the version which the "B.J." was kind enough to print, I have no reason to complain of the general trend of criticism. It is true that one scientific expert, who has probably made more enlargements than the average operator in a commercial business, bluntly told me not to make myself ridiculous by putting forward such views. But I discounted his discouragement, as he supplemented it with a dogmatic assertion that the function of the condenser in an enlarging lantern is to transform the divergent rays of the artificial light into parallel rays. After that I felt there was nothing more to be said. The "Ex Cathedra" criticism in the "B.J." of April 24 is more serious, though distinctly friendly. I note that the writer agrees that my statement of the law of exposure in enlarging is correct, provided the conditions set out in my lecture obtain; that is provided (1) the source of light is focussed by the condenser on the projector; and (2) the image of the source of light thus produced is always larger than the working aperture of the projector. A third condition, inferred in the one just mentioned, but actually expressed in my lecture, was (3) that the lantern should be properly constructed.

Now, so far as I can gather, the enlarging lantern of commerce is not constructed (as a microscope or a telescope would be constructed) with any regard to scientific principles. If it had been the law of exposure, which I have stated, would long ago have been worked out. That it has not been (if it has not been) worked out before, is to me proof positive that no scientific man has ever taken the trouble to calculate the relations which ought to obtain

between condenser and projector to secure the greatest efficiency in the instrument. It has apparently been left to mechanics to work by rule of thumb, and who say: "Here's a condenser," "Here's a lantern," "Here's a lens," "Let us fix them up together and make an enlarger."

In the concrete instance cited by the writer of the "Ex Cathedra" notes just mentioned, that critic says my theory breaks down. I do not like to dogmatise, as I have not seen or tested his apparatus, but I would humbly suggest that it is the lantern, not my theory, which is at fault. The projector, in his test, has a focal length of eight inches. Its working aperture—a most important element of the test—is not stated. I guess from internal evidence that it would be probably  $f/4$ , and that its diameter would be about two inches. With a  $5\frac{1}{2}$ -inch condenser the diameter of the effective portion of the conjugate image of the incandescent mantle, 13 inches from the condenser (as in the test), would be about  $\frac{3}{4}$  inch. Hence condition above mentioned is violated—and that is the fault of the lantern.

Again, without dogmatising, I suggest that if the writer of the note will stop down his projector (with the sharp image of the light falling on it), until he gets even illumination of the disc, his projector will pass at least as much light as it does when he throws the light image, with full aperture, in front of the projector, inches from the condenser. I suggest that he should test this making two exposures with the two adjustments. If (as I anticipate) he gets, with the smaller aperture, as efficient an exposure as he can get with the larger aperture, I would further suggest that the maker of that lantern was an unscientific mechanic, who threw away uselessly, the high power given by the large aperture of his projector. Again, without dogmatising, I suggest that he should apply the same test to a lantern working with an arc light, or other powerful illuminant, in the one case focussing the conjugate image of the light on the projector and stopping down till he gets an even illuminated disc, and in the other case adjusting, in the ordinary way, by throwing the light image in front of the projector so as to get the necessary body of illumination to fill the full aperture. (as I anticipate) the smaller aperture proves as efficient as the larger one, I would again suggest that the unscientific person who made that lantern wasted his material. He used a lens working at a large aperture, where a smaller aperture (presumably cheaper) would be quite as efficient. Assuming these two sets of experiments to be as I have anticipated, I would still further suggest that not only does my theory hold when the lens is so stopped down, but the meter will work accurately with these sources of light as long as the worker continues to stop down sufficiently to satisfy the essential conditions.

It is quite easy, I would further suggest, for any person with elementary knowledge of mathematics to calculate the conditions of construction of an enlarging lantern, so as to give the most efficient result, and at the same time to make it practically automatic in working, with the aid of the meter I have designed.

4, Ingleside Grove, Blackheath, S.E.

JOHN NIXON.

#### COLOUR PSEUDO-STEREOSCOPIC EFFECTS.

To the Editors.

Gentlemen,—I have been much interested in reading your article this week's issue on "Pseudo-Stereoscopic Effects," due to colour, and venture to give another example which has often struck me as being very definite.

There is in a church not far from here a stained glass window in which there is a central figure portrayed with a very deep cloak. After gazing at this window for a few seconds the observer produces the effect of standing right out in front of the other side of the picture, in fact to such an extent that the mental suggestion is that of a separate picture of the cloak in a different and nearer plane to the observer. This is not due to the shading or drapery of the folds of the cloak, but is undoubtedly caused by colour. There are other portions of the window equally well drawn and shaded which do not give rise to the phenomenon.

This effect is produced without the use of a lens, and is, I think, one of the most noteworthy examples which I have ever seen across of stereoscopic effect due to colour.—I am, Sirs, yours faithfully,

W. D. BORDEN.

Beacon Lodge, Bean, Dartford, Kent.

April 24, 1908.

## PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—I cannot let the continued complaints made in your evidence columns concerning the P.P.A. pass without a very protest. Apparently most of the complaints are made by people who are not members. I joined the Association when it was first formed, and ever since it has been a continued source of help to me in my business. No matter what the subject is, be it a question of infringement of copyright, or plans for a new studio, in fact connected with professional photography, my letter of request or advice elicits from the courteous hon. secretary a kindly reply by post, with advice of the very best, and to the point.

I would like to give instances: A press agency owed me money, and applications for payment met with no response. I wrote to the P.P.A., thinking the information would be of service to the committee, and not expecting them to act as debt collectors. The hon. secretary wrote to the press agency in such a way that I received a cheque from them by return of post.

I am recently rebuilding a studio. The property I had to work with was old-fashioned, and very difficult to replan. I wrote to the Association asking for ideas and suggestions. In a few days I had a plan drawn to scale, sent me by no less expert authorities on architecture than Mr. Alfred Ellis and Mr. Mackie, with the kindliest concluding remark to their letter: "Don't hesitate to let us know again if there is anything further we can do for you in this or any other matter." To add to these acts of helpfulness of the Association, I have had free solicitor's advice, 20 per cent. off fire insurance premiums, and other advantages which I will not take up space to mention.

There is only my own experience, and I know many professional photographers who have benefited quite as much as I have by being a member of the Association. I can only say, Gentlemen, that the P.P.A. of uselessness is a gross misstatement of fact. If all photographers would join the Association it, by their doing so, would be of even greater use in protecting the interests of and improving the profession.—Yours truly,  
TOM REVELEY.

London, Wandgate and Abingdon-on-Thames.

April 27, 1908.

## THE PORTRAIT POSTCARD.

To the Editors.

Gentlemen,—Having failed in business as a fishmonger, I aspired to the "profession" of photographers, as I had a little experience as a friend who possessed a camera. I thought it the easiest to commence without capital. With the aid of a showy advertisement I obtained a camera and other goods on credit at trade prices, the firm never making any inquiries at the time, though I doubt they made earnest inquiries later when I left that firm. Of course, this necessitated changing my name, and I became the photographic Fine Art Company. I did a good trade in the free enlargement business, having a number of customers, but this got rather too hot.

At the same time now I have been very successful with portrait photography. I use large quantities, and the makers scramble to supply me at any price, on any terms. (I trust you will not give credence to any of these firms who have supplied me.) Photographs will find postcards at 2s. per dozen a paying line (even if you take the orders), as the materials can be obtained practically for nothing.—Yours truly,  
A. S. WINDLER.

London, 24, 1908.

To the Editors.

Gentlemen,—To cure the profession of the postcard disease will require self-sacrifice on the part of its constituent members. The members to the "B.J." will not do it, and I do not think a cure meets the case either, for how would that affect a man who is owning, say, twenty or more studios, while it would do nothing to the already intolerable burdens a small proprietor has to bear? The cure can only be achieved by the concerted action of professional men in the country. The best way to secure the cure is immediately forming societies in every large town. Here the self-denial will come in. Organisers will be wanted to call on photographers in their town and convene a first meeting of twelve to twenty representative professionals, and then form a nucleus on which to form their society. I would suggest

that each society be a branch of the P.P.A., who would act as organisers and court of appeal, etc. These societies could arrange minimum prices to be charged by their members, and let their fellow-townsmen know the reason why.

The concerted action of the whole profession throughout the country should soon abate the fighting power of the pirates. Amateurs' back-yard work can be ignored. There are amateur bakers, gardeners, cobblers, dressmakers, etc., yet the professionals in these lines of business do not seem any the worse for it. I will say this, however. The Bakers' Association put an advertisement in the paper that bread will go up on a certain date, and on that date the little shop round the corner raises the price. Instead of writing to the editor, write to a fellow-professional and talk the matter over with him about starting a society, and do this to-night, and you will be on the right track. This applies to every pro. who reads this.

DAVID.

To the Editors.

Gentlemen,—Some time ago this matter was discussed, and it appears, from the recent correspondence, many are feeling its innovation. There is one point I should like to call attention to. In dealing with customers it is possible to convince them that they cannot expect good work at postcard prices. Without explanation they do not see why, if they can buy good portrait postcards from negatives taken by leading photographers, they cannot have theirs done at the same price. You can show them that these are only done in large quantities. If they will give an order, say, for 200 or 250 copies, then you will do them at the same price.

As a fact three-fourths only require about a dozen at any price, then you have the opportunity of doing them at 5s. per dozen, or the usual cabinet. In most cases I have found they have decided for the latter, but if any decide after all to go up the street and have the 2s. 6d. per dozen I, of course, allow them to go. It is not this that has affected the professionals' returns only, but the amateur, who takes for pleasure all his friends and gets his prints done at low prices, and where he does not actually give them away he only charges the bare cost of materials. In large centres it would be impossible to check the supply of the 2s. 6d. postcard, but in smaller towns they could be shut out if all the photographers would combine; but there is the rub, the profession is not united in any way.—Yours,  
OLD PRO.

April 28, 1908.

Several other letters on this subject must be held over until next week.

"THESE FILMS," said the photographic material merchant to the eminent judge who had recently taken up snapshotting as a hobby, "must not, of course, be exposed to the light at all." "Quite so," replied his Honour, "I understand. I shall try them in camera."—"The Globe."

WE REGRET TO LEARN of the death of Mr. Benjamin Illingworth, the eldest son of Mr. W. Illingworth, Abington Street, Northampton, which took place at Neemuch, Central India, on March 28. Mr. B. Illingworth held a very lucrative position at the head of a Bombay photographic firm, and it was while photographing in Central India that he was fatally seized with small-pox.

TO A MANCHESTER PURCHASER.—The Birmingham Photographic Company, Ltd., write: "We received a postcard this morning, postmarked Manchester, inquiring for a quotation for 'Nonstress' glossy bromide paper, 18in. x 15in., evidently the result of our advertisement in the 'Journal.' The sender not only omitted his address, but also his name. Would you mind noting this in the 'Journal,' in the hope that it may meet our inquirer's eye?"

WIRELESS TELEGRAPHIC TRANSMISSION OF PHOTOGRAPHS.—A company of journalists assembled at the Hotel Cecil on Thursday evening last to witness a demonstration of the Knudsen system of wireless telegraphic transmission of drawings, photographs, etc. Without entering into details of the apparatus, it may be said that Mr. Knudsen transmits from an original made on a thickly coated gelatine plate, in which relief, corresponding to the light and shade of the original, has been formed, which relief is dusted over with an iron powder. This original is traversed by a metal point, which transmits the electric impulses to the receiving machine, where they are recorded in dots or short lines on a smoked glass plate, from which a photographic print can be taken.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- F. A. CROOK, Oakdene, Eton Road, Datchet, near Windsor. Photograph of the East Front of Ditton House, Ditton Park, Datchet, near Windsor, and Photograph of the South Front.
- P. H. UPTON, 43, Park Road, Teddington. Photograph of a Flea.
- J. S. HEWARD, 48, Arundel Road, Littlehampton. Photograph. Shepherd and Flock of Sheep.
- H. ALLISON, 85, Clanbrassil Street, Dundalk. Photograph of the Rangers Gaelic Football Team, 1907, Dundalk.
- E. G. HARRIES, Bishop Street, Londonderry. Two Photographs of Fire at Londonderry Guildhall.
- F. H. HOWELLS, 12, Albert Road, Widnes. Photograph of Pez Mill Avenue, Cronton, near Widnes.

**DEXTRINE MOUNTANT.**—Could you kindly tell me how dextrine is mixed for mounting photographs? I seem to have failures each time.—G. W. R. W.

We presume your failure is in getting the paste to solidify, though you do not say what the failure is. The most probable cause is an unsuitable sample. You should get the best white dextrine from a reliable source; but why not buy the paste ready made?

A. K. D. (Blackheath).—We cannot say. If you will address Mr. Butt, c/o of the "British Journal," your letter shall be forwarded.

F. I. (Nunhead).—There are no books of recent date. We advise you to write Messrs. Dawbarn and Ward, 6, Farringdon Avenue, E.C., for their suggestion.

S. H. WRIGHTON.—The firm simply carries on the business of an agency for photographs intended for the Press. We cannot see that it is doing anything illegal.

**PLATE MARKING.**—Will you through the medium of your paper tell me who supplies the apparatus for plate-marking postcards in large quantities? I know the Leto people supply an amateur's method, but I want to plate-mark postcards by thousands, and cannot make a nice job of them at present.—B. E. W., Bradford.

Such houses as Houghtons, Marion's, Fallowfield's, and others, will supply the requisite appliances for plate-marking prints.

S.—A. H. Bull, 93, Harwood Road, Fulham.

**PENTLAND AND CO.**—With suitable blinds or screens excellent portraits can be taken in a studio with this aspect. Instead of having lower boards on the outside we should advise light wooden frames, covered with thin muslin or tracing cloth, hinged to, say, alternate sash-bars on the inside. These can be adjusted at any angle by connecting them, top and bottom, by a cord; they can then all be moved at once to the same angle. In such a studio as this a good size head-screen will be found very useful.

**COPYRIGHT QUERY.**—Would you kindly advise me as to the following? Having a print in my possession and wishing to reproduce same for commercial purposes, could I copyright it? There is nothing to show whether the original owner has done so. Should I be liable to any proceedings after having copyrighted the print?—DOUBT.

You cannot make another person's work your copyright, unless he duly assigns it to you. If you copy the picture and make copy of it copyright that does not absolve you from proceedings for infringement of any copyright there may be in the original picture. It is not necessary that a picture, the copyright in which has been registered, should bear the word "copyright." He who copies another's pictures does it at his own risk.

**OBSCURING GLASS.**—Will you kindly give me a formula for frosting glass? During the summer months I am troubled with very strong

reflections, but must not have frosting too dense, as it cut off too much light. An early answer in your "Answers to Correspondents" column will greatly oblige.—A. E. C.

A very good medium is whitening, mixed with starch paste. The best way to apply it is with a sponge, stippling it over so as to avoid streakiness. This frosting is easily washed off at the end of the season. A better thing than applying anything on the glass is to have some light wood frames, upon which is tissue or tracing linen. They may be fitted with two buttons, and removed at any time when not required.

H. M. K. and Others.—In our next.

**POSTCARD.**—We advise you to get the "Fine Art Journal," 11, Arundel Street, Strand, W.C. It is a trade publication, but we should think they would supply it to you.

**A SHABBY TRANSACTION.**—(1) I should be extremely obliged to give me your advice in the following case. Some time ago I took a sitter. A dozen cabinets was to be the order. I submitted the usual lightly printed proof, and in due time heard that the sitter was satisfied with it, but would like to see a proof somewhat darker than the first one. I complied with their request, but the precaution to write my name across it. I waited some time and then wrote, asking them whether I should proceed with the order. I was greatly surprised to receive a curt note, stating that they were not at all satisfied with the proof. I have since learned that the proof was finished and copied by an amateur friend, and sent to a retoucher, to be retouched, if possible. (2) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (3) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (4) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (5) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (6) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (7) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (8) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (9) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (10) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (11) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (12) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (13) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (14) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (15) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (16) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (17) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (18) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (19) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (20) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (21) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (22) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (23) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (24) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (25) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (26) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (27) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (28) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (29) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (30) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (31) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (32) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (33) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (34) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (35) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (36) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (37) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (38) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (39) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (40) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (41) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (42) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (43) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (44) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (45) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (46) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (47) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (48) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (49) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (50) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (51) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (52) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (53) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (54) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (55) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (56) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (57) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (58) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (59) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (60) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (61) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (62) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (63) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (64) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (65) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (66) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (67) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (68) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (69) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (70) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (71) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (72) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (73) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (74) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (75) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (76) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (77) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (78) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (79) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (80) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (81) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (82) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (83) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (84) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (85) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (86) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (87) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (88) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (89) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (90) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (91) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (92) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (93) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (94) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (95) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (96) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (97) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (98) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (99) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible. (100) When I became aware of what was going on I sent them a polite note, asking them, since the sitting was satisfactory enough for copying, to retouch, if possible, to be retouched, if possible.

(1) This is a very shabby transaction, but we do not see how you have any remedy, unless you proceed against the party who made the sitting and proof. (2) It would certainly be illegal to make use of the portrait as a specimen, and it might lead to a lawsuit. (3) In any case the copyright will not belong to you; it is the property of those who gave the order for the portrait being taken. We should say you would do well to retouch the 2s. as a payment for the sitting. In no case give up the negative.

R. E. WESTON.—1. We cannot explain this, except by assuming it is an effect due to a variety of halation. Try backing the negative and see if they give results free from the defect. 2. We have used this process, but it appears probable that if the first negative is too fully developed the resulting negative will be too contrasted. We should aim at a soft positive; but you should do the effect yourself, especially as you intend to apply the process to paper negatives. 3. We should not use the sulphite, but a little acid only.

\* NOTICE TO ADVERTISERS.—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

**The Bromoil Exhibition.**—Mr. J. C. Warburg, on page 356, reviews the exhibition of Bromoil prints now open at the "British Journal." Mr. Tilney, on page 359, has some notes on the seventy-two exhibited prints which form his first attempts at the process.

**The Postcard Portrait.**—In concluding the correspondence which has been running for some weeks past we have something to say of the causes for the present evil, which, as we point out, may frequently be mitigated by the exercise of tact in the reception. (P. 354.)

**Mr. W. Foster Brigham**, on page 362, contributes his experience of the use of a new printing paper for professionals.

Some topical hints for the middle-class professional worker appear on page 363.

Some maxims to be followed in posing ladies have been uttered by an American worker. (P. 364.)

The new home of cinematography organised by Mr. Charles Urban is described on page 361. At the opening on Tuesday last demonstration of cinematography in natural colours was given by Mr. G. Albert Smith.

Mr. Justice Jelf's recent decision in a cinematograph copyright case supplies, we would hope, by inference, the argument that some measure of protection for cinematograph films may be sustainable under dramatic copyright. (P. 355.)

The collotype process and the testing of shutter speeds figure prominently on this week's society reports. (P. 368.)

A criticism of the chief portraiture at the Royal Academy is given on page 359.

## EX CATHEDRA.

**Next Week's "B.J."** Owing to pressure upon our columns this week, due to the notices of the Bromoil exhibition, and other matters, we are compelled to hold over until next week the article in the series, "The Modern Note in the Design and Fitting of Photographic Premises," which deals with the design and erection of a complete photographic establishment. This appropriate conclusion to a series of articles, which have attracted much attention, will itself be signalled by the presentation with next week's "B.J." of a large supplement giving the architect's drawings of the external and internal features of the buildings. The supplement will be specially worth preserving, and this announcement is therefore made in order that those of our readers who have not the "B.J." regularly on order may not be disappointed in getting the issue of May 15.

\* \* \*

**Mr. Speaight's Marble Arch Improvement.** Everybody must surely congratulate Mr. F. W. Speaight on the speedy and successful issue of his suggestion as to the improvement of West-End London by the detachment of the Marble Arch from Hyde Park. It is only three years since Mr. Speaight, as a "citizen of London," first made known his scheme, but, thanks to the unanimity amongst the public bodies concerned, almost as remarkable as that of the departments of the Mikado's Government under the administration of Pooh-Bah, and particularly in consequence of the interest and support of the First Commissioner of Works, the suggestion has become an accomplished fact within the past few days. The story of the negotiations which Mr. Speaight has issued, lest people credit him with more than his due, makes us regret that the original scheme has not been carried out, but the satisfactory fact remains that London owes to one of her photographers the beautification of an ancient landmark, and improved facilities for traffic at a point of intense vehicular congestion.

\* \* \*

**The Real Rumford's Photometer.** By good luck we have recently been able to secure copies of Rumford's original papers on the photometer, and a study of these reveals the somewhat remarkable fact that the clumsy apparatus described in the optical textbooks as Rumford's photometer is only a rough experimental device that he never dignified with the name of photometer at all, and one that he very soon abandoned in favour of a greatly improved instrument, with regard to which he states:—"I have now brought the principal instrument to such a degree of perfection, that, if I might without being sus-

pected of affectation, I should dignify it with a name, and call it a photometer." The one-rod photometer of the textbooks was Rumford's original idea, and he described it to Sir Joseph Banks, President of the Royal Society, in a letter dated December 20, 1792, and read before the Society on February 6, 1794, more than two years later. On the same night, however, they read a second letter from Rumford dated March 1, 1793, or only a few weeks after his first letter; and this second letter described in the fullest detail what he for the first time called a photometer. This was the instrument that he did his important photometric work with, and the one that he advocated. A most essential feature of it was the use of two rods to cast shadows, instead of one, but this two-rod photometer is ignored in the books, though the descriptions of the two varieties were published together. As a matter of fact, the inefficient apparatus of the textbooks was one that Rumford condemned and abandoned, and those of us who have been forced to study it and to respect it under the delusion that it was Rumford's photometer may well consider that we have a grievance against the "authorities." The real Rumford photometer consists of two long optical benches forming an angle of 60 degrees with each other. At the point where their axes intersect a white screen is fixed exactly at right angles to a line bisecting the angle between the benches, and on each bench axis a rod is fixed, each rod being 2.2 inches from the screen and 3 inches from its neighbour. The lights to be tested are moved backwards and forwards along the optical benches, and the two lights, of course, cast four shadows of the rods. The two outer shadows are eliminated by a black screen, and also by tubes that direct the light from each light towards its own rod. The two inner shadows fall next each other, and are observed between the rods by an observer standing between the benches. The advantages of this arrangement are obvious to any one who has attempted to work with the single-rod arrangement, in which the rod most effectually prevents one from obtaining a direct view of the shadows, though a direct view is necessary to accuracy. Rumford points out that it is desirable that the shadows to be compared should be of the same width, and to effect this the rods are made to rotate, and are fitted with wings, so that either shadow can be increased to the right width. Any such adjustment is, of course, impossible with the single-rod arrangement. If compared with what is commonly supposed to be the Rumford photometer, it is evident that the real Rumford photometer is a very efficient and workable instrument, but the use of two rods and the proper adjustment of the screen are most essential features.

#### A Curious Stereoscopic Experiment.

In a book on "The Eye," by Alfred Smee, F.R.S., published in 1854, a very curious method of obtaining what the author calls a binocular picture is described. Mr. Smee, whose name is well known in the scientific world, held curious ideas with regard to binocular or stereoscopic effect, and his binocular pictures, in effect, amounted to the printing over one another of a stereoscopic pair so arranged that the principal objects at the point of sight should be in register. To produce the separate pictures, he employed a single camera arranged to rotate in an arc of a circle, the centre of which formed the centre point of the view. On the advice of Mr. Hensman, Engineer to the Bank of England, to which institution Mr. Smee was surgeon, the camera was mounted on a wheeled carriage with front wheels a little smaller in diameter than the back wheels. This ensured the camera being kept level while it was moved  $2\frac{1}{2}$  inches round the arc for the purpose of securing the two views. The apparatus was used in

Messrs. Horne and Thornthwaite's "photographic room," and on experimenting it was found that the best results were obtained when the camera was kept continually in motion, backwards and forwards through the space of  $2\frac{1}{2}$  inches. It is claimed in the book that "the character of the likeness is wonderfully improved." The experiment is a curious one, and its effects are rather difficult to understand, seeing that they are not paralleled by any modern arrangement of apparatus. If any are still in existence, they would be interesting, even if the wonderful improvement in the likeness should not be quite manifest.

#### THE POSTCARD PORTRAIT.

IN our "Correspondence" columns this week appears a further batch of letters on the evil of the portrait postcard, in regard to which we have published the views of a considerable number of photographers—with one or two exceptions, all, we should say, of the lower middle class. In closing the discussion we may comment on certain aspects of what is undeniably an evil in certain classes of present day portrait photography.

It must be admitted that the portrait postcard has now become established, and that it is being produced in some places at very unremunerative prices—in some instances, as low as two shillings or half-a-crown a dozen. But these cutting prices are mostly confined to small country places. In most middle class businesses in the metropolis the minimum charges are about double these figures, and they are low enough in all conscience for good work.

Much of the present state of the postcard trade has really been brought about by photographers cutting one against the other. Customers, it must not be forgotten, do not rule the photographers' charges, but when they are offered pictures of very nearly the same size as cabinets for, say, half-a-crown a dozen, while the price of the latter is four or five times that sum, it is not surprising that in many cases they elect to have the former.

The late correspondence has been interesting from several points. For example, one correspondent showed the very lax way in which some businesses are carried on. It was related that a customer brought to the studio four children and a dog to have them photographed in four different positions. When the work was done the customer said she would have a dozen postcards from each negative, amounting to ten shillings in all. Our correspondent bewails the fact that she did not order cabinets, as then his bill would have amounted to nearly £7. But when a business is conducted on such lines as this, we do not see that the photographer can really believe that he is doing anything but actually encouraging the evil of which he so loudly complains.

Not a few of the "middle class" really cultivate the portrait postcard by making a feature of them in their shop-windows and show-cases, and it is not surprising that by so doing they are advancing a great and growing trade evil. Some will say in defence that others are doing it, and they must follow suit. Well, that is an excuse of a kind, but the middle class photographer who is doing good class of picture should be able to ignore this type of business, and thereby maintain his status amongst his customers.

On this point we will mention a conversation we had the other day with a middle class photographer about the postcard subject. He told us he did postcards at four and sixpence the dozen, but he did not do many, as he had a clever business lady as receptionist who saw to that. She made no show of cards, but always had some handy when they were asked for. These specimens were all of a homely

of sitters, attired somewhat unfashionably. At the time plenty of excellent up-to-date cabinets kept lying about. The contrasts were great, and not the advantage of the cards. On these being considered commonplace by customers, the receptionist would mildly state that it was mostly commonplace people who ordered cards, and she would sometimes suggest that, if a portrait was not actually required, it would possibly be better to order, say, half-a-dozen cabinets, and her copies of them could afterwards be had as required. The tactics more often led to an order for cabinets than cards, and our friend added that by this lady's busyness he made very few portrait postcards, while he had many cabinets as ever.

The many suggestions made by correspondents for checking the extending postcard business have indeed been various, and some not a little ludicrous, but no really practical one has been put forward, and probably will not while there is so little unity amongst professional photographers. Each appears to look upon his fellow more as an antagonist than anything else, and there is no sign of a spirit which is often to be seen among the professional photographers of America when such matters as this are threatening the interests of the profession.

Several of the letters we have received have made reference to the Professional Photographers' Association, and have suggested it should take up the matter for the benefit of the profession generally. As a rule, these writers are not members of the P.P.A., yet they feel themselves justified in posing as censors of the Association.

As a matter of fact, only a moderate percentage of professional photographers are members of the P.P.A. If support which it deserves were granted, the P.P.A. could embark on some of the measures which present a reasonable prospect of success. Thus, if the Association had the support of the general body of the profession, and district branches, it might be a very easy matter for it to arrange a difference in the style of the postcard, so that it does not clash, as at present, with the cabinet picture.

This might be done, say, by making the postcard of only one size as could be taken on a quarter-plate and masking it, so that, with the masked border, it would fill up the full size postcard. This would be one way out of the trouble; and others would doubtless suggest themselves. But under the existing state of things nothing practical can be done.

#### COPYRIGHT IN CINEMATOGRAPH FILMS.

The *Times* of April 30 is reported Mr. Justice Jelf's judgment in the King's Bench Division of the Court, in the case of *Karno v. Pathé Frères*, the circumstances of which have a bearing of considerable importance on the hitherto somewhat nebulous question of right in cinematograph films. The case is somewhat obscure, yet the general deduction from the learned judge's judgment is that, from a legal standpoint, the reproduction of a series of incidents by a cinematograph performance amounts to a dramatic "representation." We better first give a brief résumé of the case. The plaintiff was Mr. Fred Karno, the proprietor of the sole right of representing or performing a farce or pantomimical play, which, under the title of "The Mummie Birds," twice nightly, has been performed for several years at theatres and music halls. The action was brought by Pathé Frères for damages for alleged infringements of their rights by the sale and offer for sale of a cinematograph film called "At the Music Hall." The characters in "Mummie Birds," it may be explained for the

benefit of those who have not witnessed this performance, consist of the spectators or audience, the performers and artists, and the stage attendants. Notable characters among the audience are a boy in an Eton suit and a "swell" in evening dress, who, in a state of semi-intoxication, interferes in various ways with the performance. We need not dilate, however, upon the features of the piece, except to say that in the opinion of the learned judge himself, who witnessed a performance of both the piece and the cinematograph representation, the film imitated, with considerable exactness, the incidents of the play. The action for damages arose from the fact alleged by the plaintiff that the film was frequently shown in a provincial town a week or so prior to the arrival of the living company, with the result that the latter's receipts were greatly reduced in consequence of the public having seen the same incident on the cinematograph. The questions, however, before the judge were the three raised by the defendants, namely (1) that the piece, as performed, was not a dramatic work entitled to protection under the Act; (2) that the cinematographic reproduction was not actually a "representation" of the sketch; and (3) that the defendants, by selling the film, were not causing the plaintiff's sketch to be "represented." The larger portion of the learned judge's summing up was devoted to the consideration of the first of these lines of defence, through the legal intricacies of which it is not our intention to follow him. Suffice it to say that in the light of the Dramatic Copyright Act of 1833, and of the subsequent decisions in the Courts since that date, Justice Jelf concluded that the "Mummie Birds" "had no real foundation in the way of dialogue or literary composition so as to bring it under the Act." In other words, the performance, according to the judgment, did not amount to a dramatic work, and consequently a reproduction of it by cinematograph or any other means was not a legal infringement of it. On this ground alone the case for the plaintiffs broke down, and judgment was given for the defendants. We are, however, indebted to the learned judge for his remarks on the two latter lines of defence taken up by the defendants, and it is these which have the particular bearing on infringements by cinematograph. The questions are:—(1) Is a cinematograph performance of a play a "representation" of the play? and (2) In the event of such a representation, is the maker or seller of the film the infringing party, or is the person actually responsible for the representation to be judged guilty of infringement? Mr. Justice Jelf, in view of possible appeal to the House of Lords, has pronounced on these two points as follows:—"In my opinion, if the 'Mummie Birds' were within the protection of the Act, the cinematograph reproduction of it, such as I find this to be, would, in fact and in law, be a representation of the plaintiff's sketch within the meaning of the Act. It is represented to the eyes of the spectator. If the parts were played by living persons the spectators would see them moving about and copying what is done in the 'Mummie Birds.' Mere pictures or even stationary tableaux vivants would not, I think, infringe the right of sole representation, but, as the cinematograph shows the figures just as the living persons, I think this reproduction would be within the language as well as within the meaning of the Act." As regards the point of producer and performer, his lordship's judgment (in regard to the suggestion that the defendants, who make and sell the infringing instrument, without which the infringement could not take place, and do so with the knowledge and intention that it will and shall be used for that purpose, do take an important part in the infringement itself), his lordship, we say, held that the inference in these circumstances would be held to be too remote and far-reaching in its consequences to be accepted. In short, even if the action of the plaintiff had been otherwise main-

tainable, it ought to have been brought, not against the makers or sellers of the film, but against the actual proprietors of the performance.

As we have pointed out above, this case, although not of direct importance to the cinematograph trade, yet does establish by inference certain principles which may help towards the proper protection, in the future, of films from infringement by other makers. This question, which, as a cinematograph film maker wrote in our columns three years ago,\* is "an open sore of the cinematograph trade," is not dealt with in the Artistic Copyright Act, nor, of course, in the still older Act relating to dramatic copyright, both of which legal enactments were framed years before the invention of the cinematograph. As we wrote in our issue of December 22, 1905, there would appear to be no means of maintaining copyright in cinematograph films through the Literary Copyright Act or through the Act of 1862 relating to artistic copyright. The recent judgment of Mr. Justice Jelf is the first to class a cine-

matograph representation with a dramatic performance. If, as Mr. Justice Jelf has pronounced, a cinematograph representation is an infringement of a dramatic performance, it would almost follow that the infringement of one such film by another might be the subject of action under the Act relating to dramatic copyright. Apparently, something tangible, which can be deposited as a description of the play, is necessary to establish a series of incidents in a play, and this, of course, the film itself provides. In the notorious uncertainty of the law loopholes for escape may be discovered in this argument, but an action for infringement of one film by another conducted on the above line would certainly appear worth while in the interests of the cinematograph trade. As we ourselves pointed out in the issue just referred to, protection under dramatic copyright would be no preventive of production or sale, but "if it could be enforced it would restrain exhibition, which is good enough for any film maker." It will thus be seen that our suggestion of three years ago is confirmed by Mr. Justice Jelf's judgment on the third point taken up by the defendants.

\* "B.J.," December 15, 1905, p. 993.

## BROMOILS AT THE "BRITISH JOURNAL."

For a little over a fortnight—until May 27—there is to be seen at the house of the "B.J." an exhibition of prints by the Bromoil process, which is of somewhat exceptional interest. As we have already announced, the collection of seventy-two prints owes its existence to the joint labours of Mr. George E. Brown, by whom the subjects (in Bavaria) were photographed; to Mr. Welborne Piper, by whom the surfaces of the bromide enlargements have been prepared for pigmentation by the process invented by himself; and to Mr. F. C. Tilney, by whom this last and vital part of the process has been performed, to say nothing of the co-operation of Messrs. John J. Griffin and Sons, Ltd., who made the enlargements on their matt "snow-white" bromide paper. To these seventy-two prints we have added "straight" bromide enlargements from fourteen of the negatives, selecting for this purpose negatives the character of which has been greatly modified in the bromoil print, as well as others from which but little departure is made. A further feature of interest which should not be overlooked by our visitors is the fact that the prints on

the walls represent the absolutely first practice of the process by Mr. Tilney. One or two prints of the very first half dozen are not exhibited, but with this exception the collection represents the total sum of a worker approaching the subject for the first time, and, moreover, turning out some half gross of prints in a short time. It is not our intention, nor, we are sure, Mr. Tilney's, to say this in any way as an "apologia pro suo broleole," but the fact may interest present and would-be workers of the process, whom we will now refer to the following review of the prints and opinions of the method by Mr. J. Warburg. There is further appended some brief notes on the exhibits by each of the three accessories before the act.

The bromoils can only remain open at the "B.J." until May 27, as they must then make way for the exhibition of the Society of Colour Photographers, which opens on June 1. Messrs. John J. Griffin and Sons, however, have kindly consented to show them at their "Rendezvous," Kingsway, from June 1 to 27.

### A REVIEW OF THE "B.J." BROMOIL EXHIBITION.

An interesting exhibition of an original kind is now open at "The British Journal of Photography" office. Mr. George E. Brown, on a recent trip to Bavaria, was evidently very busy with his hand camera. Of the resulting negatives no fewer than seventy-two have been enlarged by Messrs. J. J. Griffin and Sons. These, after being bleached by Mr. C. Welborne Piper by his Bromoil process, were pigmented by Mr. F. C. Tilney. Every print has, therefore, been through the hands of four different individuals, each of whom has had an influence on the result. In many instances untouched bromide enlargements are shown side by side with the bromoils, enabling a useful comparison to be made.

Mr. Brown does not pretend to be a photographer of great pictorial prowess, though his two pictures at last year's R.P.S. (one of which hangs at the portal of the Bromoil Exhibition) show that he is more modest than need be. His "raw material," as it appears in the comparison prints, is generally well arranged and good in composition; but the use of a hand camera and non-orthochromatic plates, followed by bromide enlargement, has given somewhat hard prints, whose aerial perspective and tone values are not always quite up to pictorial standards.

It is the more interesting, therefore, to observe to what extent Mr. Tilney (who is by profession a painter and draughtsman, and to some extent a photographer) has been able to remedy these faults, while making the most of the virtues of subject and composition.

The following examples will serve to show what he has done. In No. 64, a shepherd is following his flock, which is grazing on the brow of a hill. The original shows a blank sky, a monotonous stretch of grass, unbroken by any line or shadow, and a hard-cut edge of hill against the sky. In the bromoil the edge has been softened. By introducing a distant star on one side of the sky, this has been pleasingly varied, and interest and centre of attraction given to the composition. The evenness of the grass has been broken up, though I think I remember Mr. Tilney himself saying at a lecture he once gave, detail did not need breaking up. This has given variety, at the loss of texture. The grass was undoubtedly grass before, but now parts of it might be snow or water.

No. 57 shows two ladies in a strongly sunlit street, at the end of which stands the Church of St. Lawrence, Nuremberg. Mr. Tilney has softened the edges of the sharp shadows,

ed the sunny effect, besides needlessly removing the lines flagstones. Here Mr. Brown scored better alone.\*

No. 40 the characteristic square tower which forms the of interest is given greater importance by the introduc- a white cloud behind it. It is a pity the square build- the left could not have been eliminated. In this print, the first one described, the inherent photographic quality en kept.

No. 58, the foreground flock of sheep, the rather black in the mid-distance, and the hard hill edge behind, have n softened and brought into harmony, with perhaps a loss of character in the sheep. Much the same might, r, have been done in another process by making a very int.

No. 9 and 12, the photographic effect has been lost with- n an artistic one. These, I understand, were early nents in the process. It may be said that the result achieved by Mr. Tilney is to soften down the uncompromising photographic effects of sharp focus and hard development, to simplify detail, and especially to ce aerial perspective where lacking; results which can eat extent be obtained more directly by careful differ- n of focus, soft development, and the choice of broad g (not quite easy matters when on tour with a hand where time is precious and opportunities do not recur). dded to this is the very effective introduction of cloud and the massing of light and shade, possibly obtainable, th somewhat less freedom, by double printing and g down parts of the print.

No. 7 is a good example of some of these points; the fore- heaps of hay are less wiry, and the leaves of the trees tly and better massed, while the Castle of Gösswein- n pushed back to its proper place in the picture.

No. 22, there was a monotonous distribution of light and the whole picture being more or less of medium tone, he sunlit grass, owing to the colour-blindness of the sed, was much too dark. Here Mr. Tilney has imagined shadow covering and binding together the foreground ht side, while the lightened hillside on the left correctly ts sunlit grass, and leads the eye to the now distant mplied Castle of Harburg, behind which appropriate ave been introduced. Here, then, not only have values erial perspective been improved, but a rather esting composition has been redeemed and made sque.

No. 51, "The Innkeeper," the general effect has been sim- but at the expense of richness of shadow detail in tant house, of character in the face, and texture in te shirt sleeve. The preservation of texture and modu- n light tones seems to be a serious difficulty both in process and in Mr. Piper's modification. In this case abtful if the bromoil is an improvement. The richness distant shadows has been lost, though the process is ose richness is, to me at least, its greatest attraction. ave piled on more ink on the figure, to differentiate the background, than have lightened the latter and "quality."

No. 7 is a similar case. The Jena market is full of peasant at their booths. In the foreground sit several of them eir curious baskets. Mr. Tilney has laudably tried to them from the confused mass of humanity behind them, s pushed back the distant houses; but more might en done. The distance could have been lightened, or till, evened up a good deal more; while the actual the woman in front, might have been strengthened. de more telling.

ney, in his short article on page 350, refers to the difficulty of retaining e light passages.—Eos. "B.J."

In No. 21, another presentment of the Castle of Harburg, a very interesting and dainty sky has been worked in.

Most effective of the whole collection is No. 33. Here we only have the finished picture, and are not shown the raw material. The centre of the composition is the Church of Gösswein-stein, sumptuously treated, with beautiful lines of architecture, as tender yet as incisive as if drawn by the hand of an etcher. Whom are we to praise for these? A very fine-sky sets off the picture, which has the darker tones massed towards the centre. This picture gives one the pleasure of a fine engraving or etching.

Just a few notes on some other exhibits. In No. 19, the experiment has been made of introducing an effect of mist rising from the water. The experiment was worth making, but it is a question whether it is often possible to represent convincingly a state of atmosphere very different from the actual one present at the time. No. 8 is a group of two girls with a very humorous expression. No. 69, of a farm labourer and pig, also strikes a humorous note. No. 2 is a broadly treated portrait of a member of the Zeiss firm of Jena. Dr. Wandersleb is shown in profile sitting at a desk. In his hand he holds a sheet of white paper, which by its high tone first attracts the eye. As the most conspicuous part of the composition, it should have had the interest given by delicate modulation and lighting; but it has none, except that which one stroke of a brush has made. In consequence the work, as a picture, fails, in spite of its other good points.

I reserve No. 68 to the last, to point a moral. It is a rich print, in which the Burgomaster's Franz-Hals-like frilled collar contrasts with his black robe, and forms a good setting to a fine characteristic face. Has the most been made of the opportunities? I think not. In parenthesis I will remark that when a man has been dabbling away at oil or bromoil prints for weeks at a time, his elbow and wrist become abnormally muscular; and it is therefore with some trepidation that I venture to criticise Mr. Tilney. Still, in the cause of Truth and Art, one must incur some personal risk.

Why I quarrel with Mr. Tilney is this: the oil process, as also its modification, is pre-eminently suited, by its rich quality—what the French call *matière*—to give luscious shadows and rich contrasts, such as we meet with in good etchings. Here was an instance where the most might have been made of this quality. There was no reason why the ink should not have been loaded on to the black robe, close under the collar—why a pure white should not have been taken out of one of the frills next to it, so that the light should *sing* out. Instead, the ink has been loaded on to the skirt of the robe, where it does not tell against a high tone, and the effect of climax is partially lost.

It has been Mr. Tilney's aim throughout to preserve the "photographic character," while increasing or importing the pictorial element; and this he has, on the whole, done excellently well. What, however, he has sometimes considered too little, is the "character of the medium." As M. Demachy pointed out in a recent article in these columns, there is no point in imitating platinotype in an oil print, nor, I hasten to say, has Mr. Tilney done so. To improve tonality and eliminate disharmonies is more meritorious; this Mr. Tilney has done very fully. Thirdly, to bring out those qualities of the process which differentiate it from other processes, this is the *summum bonum*; and this height Mr. Tilney has not very often reached, though in some of the pictures he has done so. Doubtless, to pigment another man's prints, without knowing what was the sentiment or motive which originally inspired them, is not calculated to produce complete unity of result. In taking a negative intended to be produced in oils, it would be well to bear in mind the qualities of the process, even when composing the picture; to choose street scenes where rich shadows contrast harmoni-

ously with high-lights, or figures in whose draperies there is the opportunity of recording or introducing a culminating high-light.

When we think of the story of Dr. Jekyll and Mr. Hyde, we become aware of the danger there might have been of the pigmentor upsetting and reducing to nought all the intentions and ideas of the photographer. This has not been the case. Mr. Tilney has loyally built on the sound foundations provided by Mr. Brown, and the result has been a most interesting exhibi-

tion, teeming with good things, and reaching in many cases a high level of excellence.

Even from those works which have not reached the high water mark of success, much may be learned; while a comparison of the bromoil prints with the straight bromides from which they have been produced, cannot fail to give an insight into the possibilities, the advantages, and the disadvantages of this ingenious process.

J. C. WARBURG.

## THE SOURCE OF THE NEGATIVES.

The photographs which form the basis of the present exhibition were all taken during a short holiday snatched last summer from the duties of Wellington Street. At the time they were taken I never had any intention of offering them up in this way, but when the idea of a Bromoil exhibition presented itself they were ready to hand, as so much raw material which could be rapidly brought into a condition for use in the Bromoil process. The fourteen enlargements which are hung above the Bromoil versions of the same subjects fairly represent the sort of results which any of the negatives will give without any doctoring whatever. As most of the exhibited pictures include the full amount of subject on the negative, a short account of the apparatus used in getting them may perhaps be of some interest. Without exception every negative was made in a hand camera, and, except the indoor portraits, Nos. 1, 2, and 4, all were taken with the camera held in the hand.

The camera was a focal-plane reflex, my experience of which has certainly caused me to prefer such an instrument to any other for the purposes of tourist photography. I may not speak for the habitual traveller who requires souvenirs of the places he visits, but has no particular cause for regret if he does not get them. My own position is usually that of the person who can spare only a week or two in the year to visit a strange country, and, there-

fore, must needs do his photography as quickly and as certainly as he can, even at the cost of some personal inconvenience. And from this point of view I most positively give my support to the reflex camera. The points of view from which the exhibited pictures are taken may perhaps be judged to be bad; but good or bad, they were often the object of a great deal of care, which, nevertheless, thanks to the reflex, was expended without waste of time. A great many of the subjects required a liberal use of the rising front. Nothing easier, when all else was ready, than to hold the camera level and raise the lens until the desired subject was included. One could dilate, too, on the easy employment of a long-focus as a hand camera lens when fixed to a reflex, and again on the equally valuable use to be made with a lens of large aperture. The luxuries of practice have been talked about by several reflex users, notably by my friend Mr. W. Thomas; but I may instate them once again in reference to the present exhibition, which affords a fair number of examples of the accuracy of adjustment obtainable with the reflex hand-camera. Those unconverted to the reflex must take my word for it as to the quickness of the reflex in comparison with a stand camera, and as to the large percentage of negatives which one gets containing just the amount of subject desired.

GEORGE E. BROWN.

## THE PREPARATION OF THE PRINTS FOR PIGMENTING.

The process of preparing a bromide print for pigmenting was described in the "B.J." for March 27, and it is unnecessary to go into the same details again. There are, however, some points that I had not then space to discuss that are worth consideration. It should be noted that different brands of bromide paper require somewhat different treatment. In some the gelatine appears to be soft and liable to rot in the preliminary treatment with acid, while in others it will stand the acid treatment for hours without any ill effects. Also some papers will stand far rougher methods of pigmenting than others. It is, therefore, very advisable to keep to one brand of paper and master its peculiarities. Generally papers with a "natural" or semi-matt surface work best. Some matt papers also work very well, but a few do not. Gaslight papers, coated with a slow bromide emulsion, are very workable, but chloride papers seem to be useless.

The original bromide should be full of detail and vigorous. It must be fully but slowly developed. If rather fully exposed it will acquire density very rapidly, but the result is then not well suited to bromoil. As regards developer, amidol is recommended, but others are nearly as good, while some seem to be nearly useless. With metal, for example, I have invariably failed, and rodinal generally gives unsatisfactory results; but in this matter I think a good deal depends on the paper used.

If the print is to be completely pigmented, that is, if all the original image is to be covered by pigment, very little fixing is required, but if any portion of the image is to be left unpigmented the imperfectly fixed image will darken by exposure to light, therefore longer fixation is desirable. The colour of the final image depends a good deal on the time for which the acid is applied, and upon the time of fixation, and also upon

whether the fixing bath contains sulphite or not. The sulphite is added to this bath to preserve it from the effects of the acid carried into it by the print. If, however, the acid is washed out before fixing the sulphite is unnecessary, and when it is omitted a faint brown image instead of a green one remains. This is much less conspicuous, therefore it is as well to leave out the sulphite if the result is to be vignetté.

If the pigmenting is to be carried out as soon as the print is ready, I generally adopt the quick method of preparation described before; but if the print is to be dried and pigmented at a later date, I give it a longer treatment, washing more thoroughly between the baths, and fixing very completely. It will be found that complete fixation gives much greater relief in the final result, though it is not clear whether this is any advantage or not.

When obtaining the ozobrome it is as well to ask for the ozobrome solution for bromoil, as the one best suited to the ozobrome process is not necessarily the best for bromoil.

Temperature should be looked after carefully, but in this there is a certain amount of latitude, varying with the time of year and the paper used. This is another fact that renders it desirable to keep to one brand of paper. I have met with one brand that requires solutions at 70 degrees F. in the winter but is spoilt in the summer by anything over 60 degrees.

As regards the final result this need not be the same as that obtained by the ordinary oil process. In bromoil the image retains the pigment more readily, and it is more difficult to alter the original drawing; but it is just as easy to correct its values, if they require it, or to add emphasis where wanted, and these qualities of the process will be seen well demonstrated in the prints now on view.

C. WELBORNE PAPER.

## MY EXPERIENCE IN THE PIGMENTING OF BROMOILS.

The Bromoil process has proved of exceptional interest to me. When all goes well the working out of one's notions seems delightfully easy, and is certainly fascinating. The photographic image is always within call when it is needed, as it is at times when one's enthusiasm leads one to safe shallows. Directly there is a feeling of floundering or two straightforward taps—cries for help—bring us with relief to the outstretched hand of the negative. As a matter of fact, one's experience of this particular variety of methods results in the conviction that the more respect one preserves for the photographic image, the more satisfactory is the final result. It is probably unwise to depart from the form and effect of the image unless there is pressing need to do so. In one or two examples in the present exhibition a frank attempt has been made to give a natural effect different from what a straight print would show. The best example of this is in the scene of the shepherd and his flock on a hillside in early morning mists, through which the sun struggles. (No. 58.)

A bromide print above displays no mists; its sunshine is bright, and its distance full of tone and vigour. Such essays are experiments to see how far the process will go in the direction of such whims, and there seems to be no limit. This particular print was pigmented with a weak and soft ink, consequently the textures are smooth and the tones even and soft. Detail is not lost to any extent—not more than it can be in such an effect in actual nature; but the gain in softness and homogeneity will, I think, be easily apparent. In the picture of the burgomaster, No. 68, an extremely strong effect is used, with the result that the robe and parts of deep tone are "ch and "fat," as engravers say. As a matter of fact the direction of the pigment makes or mars. If it is not exactly right for the subject it gives a lot of trouble. I have found it difficult to make my own pigment with "levigated" dry pigment mixed with varnish upon a slab with a muller. The necessary touch of oil may be supplied from a tube of artists' varnish, and that will also give some latitude in the matter of tone. A good black broken with yellow and orange tints gives a nice variety of greeny blacks, which are a relief when one is tired of the hot brown and amber colours. When said and done there is nothing so generally suitable, so

intrinsically lovely, nor so wide in scope as black. Stiffness or softness of pigment depends upon the relative proportions of varnish and oil. Some of both are always necessary.

The brushes (and I had the best that money could buy) I found a vexation of spirit. They chip and split and shed little bits of hair all over your print. These bits have to be cleaned off afterwards, together with specks and other unwanted morsels, when the print is dry. I have found only one method that does this important, but tedious and irritating work adequately, and that is the use of a sharp eraser or scalpel. The whole length of the edge may be lightly driven to and fro over the print, not vigorously enough to scratch. Whatever this fails to remove, the point of the instrument may. Sometimes a hair will jump off, and yet leave a mark. Then the operator must skill himself to hold his knife so that a white-scratch will exactly coincide with the black one and neutralise it.

The attentive spectator will see many little differences between the bromides and the bromoils shown together for comparison. Much may be done in altering little matters of composition, or in omitting some items altogether, although less is possible by this method than in the Rawlins process. Here and there a figure has been so lightly pigmented as to match exactly its surroundings, and so disappear altogether. This, of course, requires much patience and some sweetness of temper.

There is only one matter wherein I have had to admit myself as beaten beyond hope. It is that where detail occurs in a light passage I have been quite unable to capture it. Consequently many sunny pavements, textures of sheets of paper, and other surfaces, and similar arrangements of delicate detail in high tone do not appear at all in the prints. The high tone becomes simply white paper, and even by debasing the tone not much can be gained.\* If in other respects the subject is one of great contrasts in tone, the case seems to be a degree worse.

The few bromide prints are hung upon the *ex pede Hercule* principle, and are not special instances. Every print has been "controlled," though many look innocently "straight." The skies are in all cases adventitious. F. C. TILNEY.

\* Mr. Warburg in his article on page 356 instances this same defect in the case of several of the Bromoils. — EDS. "B.J."

## PORTRAITS AT THE ROYAL ACADEMY.

It can be admitted that there are few works of great power in this year's exhibition at Burlington House. We deal here with portraits only; but in every branch there is the same lack of something that rises much above a dead level of general merit.

The enthusiast who visits the Academy in the capacity of a collector looks eagerly around for the Sargents. When he sees a Lady Sargent he has the comfortable feeling of expectation gratified. In the present exhibition the Sargents are not quite up to the standard. Just a degree below it, however, comes "Huth Jackson." The lady sits upon a high-backed couch of drabby-white satin now quite recognised as part of the in-trade of Sargent and his satellites. Her dress is of satin also, and a white Indian shawl, with its coloured forms part of the attire. The accent of colour comes in mon-tinted cushion against which the lady's head is gently pressed. The ease and grace of the design, and the beauty of the subject, will no doubt make it the favourite this year. Painted with all the artist's marvellous directness, but with more completeness of realisation than usual, who call Sargent's method "slapdash" are hopelessly wrong; the mark; there was never a painter who worked with more care. In the other chief work of this season, the portrait

of the Duke of Connaught, this careful realisation of everything is still more clearly shown. If one compares Sargent's painting of the Duke's sword-hilt and handle, or the gold cords of his uniform, with similar details in any other portrait in the galleries, the difference is remarkable. Other men's swords are much more flimsily sketched, and simply stand for what they represent by tacit understanding of the spectator. In Sargent's case the things are solid presentations, not "suggestions." The Duke's portrait is a fine work. It is not in silks and satins alone that the master finds his supremacy. The smooth nap of straight hanging cloth is quite as wonderfully given, and the Duke's coat puts to shame many a "brushy," "painty" patch of work that hopes to be passed for a coat in other portraits. One does not see paint at all in this portrait. The head is a round, solid thing, the face shows all the textures of the skin of a man getting on in years, a matter wherein the painter spares not his most aristocratic sitter. We see, just as well as if we were talking to them, exactly how Time has dealt with both Duke and Duchess. Both of them are dignified and of truly noble and gentle bearing, but neither are flattered back into their prime. Indeed, Sargent is the very reverse of a flattering retoucher—he can afford to be. His portrait of the Right Hon.

A. J. Balfour, M.P., is exactly what it would not be if Reynolds had painted it. That master would have laid himself out to design something to be considered worthy of a statesman, using accessories of all kinds to build up a monumental work that should make posterity think the sitter a greater statesman than perhaps he really was. Sargent gives us Mr. Balfour pure and simple. No doubt the sitter looked rather dwarfed before the immense column against which he leans. No doubt his unassuming manner, his modest black clothes, and so forth, were not exactly in the grand style; but here he is as he was, and he does not seem to have inspired Mr. Sargent, who has spared not a jot of the realism. There is a touch of the satirist in the painter.

Solomon and Shannon between them divide the honours of the show after Sargent. The large panel decoration of the former is a complete success, entirely suitable for its monumental purpose, and yet quite charming and attractive in other ways. It is called "Mrs. Alfred Mond and Her Children." The lady stands proudly and gracefully between her two children, one of whom is upon a chair, and nestles its face against the bosom of its mother, who lays her left hand upon the shoulder of the other child standing at her knee. The group is skilfully arranged and extremely pretty. The sitters are in a richly furnished chamber, affording a fine display of accessories painted with sufficient realisation, though keeping their place, and answering their purpose of general aggrandisement. Mr. Solomon's next best portrait is perhaps that of "L. B. Abrahams, Esq." Here he makes use of the hood and gown as a relief to the unpictorial male costume of moderns. All such insignia of art, letters, law, court, Army, or Navy seem, naturally enough, to be eagerly pressed into service, and meets one's eye at every turn. This particular subject is one of great animation, representing the sitter seated holding a book, a finger between the leaves, and the other hand held up towards us as though in emphasis of some argument. The face has a smiling expression that entirely saves the subject from any charge of over-demonstrativeness.

"H.R.H. Princess Patricia of Connaught" is by J. J. Shannon, and will certainly enhance his reputation as a portrait painter. The Princess sits with one arm over the arm of a chair whilst the other lies in her lap, and her fingers toy with a long pearl necklace. The head is posed in a very happy manner, being practically in profile, but having a slight upward tilt. The eyes being more directly turned towards the spectator. A more ambitious work by Mr. Shannon is "The Marchioness of Salisbury and Lord David Cecil." Little Lord David sits upon a stool at the knee of his mother, who is attired in black satin. Both the sitters are shown to be raised upon the studio throne, and that in spite of the ordinary palatial background. This I would humbly suggest is an error of judgment, but the great merits of the work as a painting overwhelm all such minor considerations.

One is glad to find that Mr. A. S. Cope continues strongly to hold his own in spite of the newer associates who paint portraits. The best of his works is perhaps "The Marquess of Bristol," wearing a naval uniform of which the dark blue cloth

and gold are splendidly managed. The whole thing is strong and restrained. Less so is the "Mrs. Moreing," which is a little fussy by reason of its accessories. "Henry Cosmo O. Bonsor, Esq.," shows an easy pose, the sitter's right hand resting upon a table low enough to give just a little movement of line to the upright figure. Other works by Mr. Cope are worthy of note, and testify to his sound and trustworthy methods.

It is with a little disappointment, however, that one looks at the portraits of Mr. Bacon and Mr. Henry, and even Mr. Lambert, less fine this year than usual. Why do painters "go off" at certain times? Mr. Bacon has an immense equestrian group which can only be described as uninteresting in subject and unfortunate in design, the chief field of the canvas being filled with the sprawling legs of a great horse and some high "painty" dogs who leap about like imps. It is all very unimpressive, and Mr. Bacon has thought fit to reverse a general custom by painting his lady rider from the side upon which her horse does not fall, hence the portrait is of a horse with a lady's accessory. In the case of Mr. George Henry one must quarrel so much with his intentions, which are at least honorable; but he has nothing so arresting as his works of former years. His highest attempt, according to some critics, is "Ermine." It is a study in greys, and although nobody would deny that it is chic, nobody ought also to deny that it is lovely, and is as flat as it can possibly be. Half a dozen portraits from Mr. A. Hacker do not stir one to any new sense of power, though it may be mentioned that the lively and voluble "Arthur Serena, Esq."—a contradiction in terms—arrests by the snapshot appearance of the pose, so lifelike and admirably caught, though not exactly dignified. The sitter carelessly lolling upon a chair with his legs crossed and his thumb in the armhole of his waistcoat.

The portraits by Herkomer are what they have been for many years now, virile, but entirely without subtlety. His method of rapidity and his short cuts to colour find their culmination in the immense canvas of "The Council of the Royal Academy, 1907," a row of life-sized portraits monotonous in colour and alike in their sketchy brown shadows. The chief interest to spectators seems to lie in identifying the several characters in the group.

There are many other interesting things that should draw attention. Dicksee's portrait of "John Belcher, Esq., A.R.S." is well fitted with a background of sculptured frieze against which a T-square rests. The happy action in the portrait of "Ruth, daughter of C. A. Cripps, Esq., K.C.," is also noteworthy in the same painter's pleasant picture of a young lady throwing off a cloak from her shoulders. The shades of purple here are well mastered. A sumptuous costume piece is Lord Dail's "Olivia" portrait, where the large red robes make glowing colour. But when one gets away from the few leading works there is no knowing where to stop, and this critique has been done so with a parting recommendation to the smart and changing picture of a young girl sitting self-consciously in a dress of green and blue shot-silk. It is by Mr. T. Mostyn, who calls it "Miss Importance."

F. C. TILNEY

FRANCO-BRITISH EXHIBITION, 1908.—In honour of the French Minister of Commerce and Industry, Monsieur Cruppi, under whose patronage the French section of the Franco-British Exhibition has been placed, and Monsieur Cambon, the French Ambassador, a luncheon will be given at the Grand Restaurant in the grounds of the exhibition on Friday, May 8. The Duke of Argyll, Lord Derby, and the members of the Executive and Finance Committees, are inviting a large company of distinguished people, including representatives of the leading French and English journals, to meet their Excellencies, and during the morning the guests will have an excellent opportunity of inspecting the exhibits in the various buildings.

THE NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY'S Year Book gives abundant evidence that the enthusiasm and activity which have always been one of the society's characteristics have in no way abated, and the list of lectures, etc., shows that all branches of photography receive their due share of attention. The record section, the special object of which is to obtain records of objects of historical and archaeological interest in the northern part of the county of Middlesex, has already collected over 200 such, which have been placed on loan with the Hornsey Central Free Library, where they may be seen on the usual reference library conditions. The list of outings contains two with special reference to this branch of photographic work. The hon. sec. is Mr. S. C. Puddy, 87, Crouch Hill, N.

## CINEMATOGRAPHY AT URBANORA HOUSE.

Friday last the Press were given an opportunity of seeing the establishment which the Charles Urban Trading Co., Ltd., has built and equipped within the almost incredible time of eighteen months in Wardour Street, where it lifts its head high above the chimney-

of Paris in London, a building without a counterpart in any part of the world. What would Dr. Paris, in 1826, have thought, as he twiddled his matrope, had he been told that its lineal descendant, the film cinematograph, as represented by the business of one firm, would revere for its housing a great 'block in the East-End of London, a staff of mechanics, technicians, scenic artists and photographers, and its emissaries in every corner of the globe? Such a dream, if it had ever been experienced, could scarcely have become the fact to-day if the cinematograph had remained mere means of light entertainment. To

Charles Urban belongs the credit of pushing forward the use of the cinematograph as a medium for the dissemination of knowledge, as the most efficient and pleasant of all "popular educators." Yet, to say that of the director of all things "Urbanora" is to do Mr. Urban scant justice. With a highly developed sense of the functions of a showman, Mr. Urban has been fortunate in adding the possession of genius to the way of mechanical invention and design, in originating a thousand uses for the cinematograph machines of his creation, and, lastly, of infusing into his colleagues the restless energy of his personality. The crowning achievement of this determined use of steel and indiarubber is the Urbanora House in Wardour Street, where, short of film manufacturing, everything which has

to do with the cinematograph—cameras, projectors, lamps, positive and negative records—is made and produced under one roof. To say that Mr. Urban "received" his guests is a poor word. He instantly bore you up high in an elevator to the roof-garden studio, led you down the outside of the building into machine shops, tried you into a basement room of printing and developing rooms, projected you back again into the board room, and left you to discover the welcome shelter of a buffet, as he caught sight of a new party of Pressmen certain of their way.

The establishment at Urbanora House is approached from the ground floor by a tribune on which opens immediately a projection theatre capable of seating 250 people, and fitted with complete lantern and cinematographic outfit installed in a fireproof chamber. Purchasers and hirers of films can here see themselves the latest creations of the Urban operators and their studios. The business offices, counting-houses, and other offices are on this floor, which, like other parts of the building, handsomely fitted. Numbers of coloured cartoons by Japanese artists of scenes in the Russo-Japanese war are a reminder of the

wideness of the sphere in which Mr. Urban's photographers have worked and are still engaged in making animated records.

The basement floor of the building is, perhaps, the most interesting. In one room a dozen of the Urban-Joy perforating machines are at work, giving the film its two edgings of the apertures by which

it is accurately guided through the taking camera, and, as a positive, through the projector. A machine for this purpose calls for an almost incredible accuracy of adjustment, since a tiny error in the making of each perforation is added up, hole by hole, and produces a film which fails to give its proper effect on the screen. At the same time it is necessary to be able to set the machine in order to allow for differences in the stretching power of the celluloid, differences in the working temperature, etc., all of which are provided for in the construction of the perforator which bears the names of Urban and Joy. Once started, the machines pour out perforated film into baskets, from which it is quickly wound into rolls by hand. The machine which prints from the negative bands on to the positive film are similarly adjustable to allow for the density of the negative and the speed of the emulsion. In one small room we saw twenty of them unattended turning out the positive films which are used in the

lantern. Development of the negative and positive films occupies another adjoining room in the basement, where the film, in 200ft. lengths, is coiled on the upright pins of the developing board, and, thus mounted, developed, fixed, washed, and sent by lift to an upper floor to be quickly dried on six great drums or reels. On these rapidly revolving reels, driven by dynamos and capable of

exsiccating 12,000 ft. of film an hour (a startling record which includes the time occupied in laying on and taking off) the process of drying is accelerated by a system of Mr. Urban's own devising, by which the air is drawn in through dust-filters, over a series of steam radiators, and the resultant hot, dry air passed through the reels by powerful electric fans. The tinting of the films—blue for night and yellow for sunshine effects—is done in another adjoining department; but the Urban Co., as we shall mention directly, is engaged in perfecting a method of cinematography in natural colours by a modification of the three-colour process.

Next, perhaps, in interest is the studio on the fifth floor. The whole of one side is open to the sky, and provides the full illumination necessary for the taking of a cinematograph film of a

series of incidents. Instead, a battery of arc lamps allows of the work being done at night. This "studio" is more like the stage of a big theatre than any other place, and is supplied with scenery such as a theatre would be glad to have, for the background of animated photographs of the story or trick class. A floor higher still, a raised concrete platform, some 40 feet square, perhaps, forms the roof of

the house, and is to be used for still other subjects, which can be handled better than in the studio below. We stand here a few minutes looking down into the narrow streets of Soho. Below is St. Anne's Church, the Palace Theatre a little further east. North, south, and west there are a hundred landmarks to be picked out from this building, which shoots above the tenement and little roof gardens such as Mr. Pinero must have clambered up to when he was producing "Letty."

We descend by external iron stairways to machine shops where the cinematographs are made for the market, and come to Mr. Urban's private office and work-room, where, on a miniature screen the films are "edited" before publication, and new features in apparatus put to the test. Somewhere here is the colour department of Mr. G. Albert Smith, consisting of sensitising, drying, and developing apparatus, which can be handled in perfect darkness. We descend again to the street level, having seen, but, we fear, very imperfectly described, a marvellously organised establishment. The Urbanora House, in its extraordinary provision for the rapid and efficient production of its commodities, excites our keenest admiration. Mr. Urban's factory, show-rooms, and offices, all working with a maximum of efficiency, represent a triumph of technical organisation, and no one, we imagine, who has the good fortune to make a tour of Urbanora House will be able to refrain from adding their personal congratulations to ours.

The opening of Urbanora House was appropriately made the occasion for the first public demonstration by Mr. G. Albert Smith of the system of cinematography in natural colour on which, with Mr. Urban's encouragement, has been engaged for years past. We saw the "Colour Photograph Supplement" of December 6, 1907, of a preview of these same specimens, which, as Mr. Smith points out, are experimental results, made to test "workability" of his process, and not with a view to publication. Nevertheless, the audience of that week, and again on Monday last, endorsed the good opinion which Mr. Smith employs a colour method, and apart from the special sensitising of the to red and green, and the use of taking and projecting film departs in no way from regular cinematograph practice—that is to say, uses the standard film, standard machine, and standard perforation. Though the films of character are not at the moment available, were, indeed, put forward by the Urban Co. in demonstration of what so far has been accomplished. These facts and the striking results obtained should promise a speedy commercial introduction of the system. Mr. Smith employs taking and projecting screens of orange and blue-violet, and though he sacrifices a little, the whole effect is extraordinarily good. The pictures are the width of the film, and alternate along the length of the band.

## NOTES ON THE NEW "ARTISTA" PRINTING PAPER.

AFTER albumen gelatino-chloride, then collodio-chloride, and now, after a number of years, something really new in print-out papers.

How precisely it can be described, except by the rather striking name with which Messrs. Houghtons have christened the new departure, we are unable to say, for herein lies its chief claim to distinction and popularity, there is no trace of emulsion about the paper. What this means is easily apparent; there is no surface to stick or crack or to give the finished print the old photographic look; no surface to show up the spotting colour or more elaborate aerograph work; and lastly, a range of eight surfaces, including a very beautiful screen grain and vellum that are different to any other process, and of a nature that recommends them to all who appreciate the artistic effect that a natural paper with its attendant dead matte can give. Add to all this the ease, quickness, simplicity, and certainty of manipulation, as well as the cheapness of print-out papers, and we have "Artista."

In the concise directions various baths and procedure are given for securing a great number of tones, and mere following of the directions and a trial print or two will demonstrate better than we can describe the colours available.

Any printer used to C.C. will be quite at home with "Artista" printing being of very similar depth to that process. For warm tones obtained in gold bath print but very little darker than required when finished. For two-bath tones, whether in gold ammonia or salt, followed by platinum (or for fixing only), printing must be considerably deeper—say, until the highest light is fairly tinted; any clogging of the shadows will disappear in the baths.

It would take too much of our space to describe all the colours and the way to obtain them, but a slight idea may be given of the directions will supply the necessary formulae.

The easiest tone to get is a pleasing terra-cotta, obtained by washing well and fixing. A still warmer tone results if a salt bath is interposed between washing and fixing. A long range of warm tones, from red-brown to portrait-purple, result from washing in the gold bath afterwards and fixing in the usual way.

This reminds us that one of the chief characteristics of the paper from the manipulative point of view is the extremely small quantity of precious metals, whether gold or platinum, that is used in toning, and also the speed of toning. This very speed

first disconcerting to printers used to the slow toning of the al print-out papers, and until experience has been gained may d to uneven and too much toning. For instance, for a warm own the change of colour in the gold bath is practically impercep- le, and, after fixing, the print will appear much too warm; as print dries, however, the tone gets colder, all the red look dry- out of it. For this reason, to secure certainty of results the ing baths must be made exactly to formula, using the same care when compounding a developer. If the bath of constant and own strength is kept at a fairly equable temperature it will be nd that timing the prints will, at the start at least, be the best de for toning. The nearest approach to sepia, as distinguished n browns, is secured by washing as usual and then placing in the monia bath until the prints are thoroughly yellowed. The prints st now be thoroughly washed to remove all trace of the ammonia, the platinum bath will only tone when acid. After washing, say, ten minutes, fix in the ordinary way.

o much for the warm tones. The black tones obtainable, how- are, we imagine, the ones that will rush "Artista" into popu- ly, for the black is of that purity confined in the past exclu- ly to platinotype paper, a paper the "Artista" resembles very ngly in surface and ease of working-up. To obtain these per- blacks, "Artista" should be treated exactly like a collodion er—that is to say, the procedure is:—Washing; tone ly in gold, say, for ten seconds; wash thoroughly for ten tes and then tone in the platinum bath, in which the prints y quickly lose all warmth; afterwards another washing to oughly remove any trace of acid left from the platinum, and fixation as usual.

he paper tones so easily in platinum that the gold bath has not eat an influence on the finished result as with C.C. paper, but ery-brown tone will be about right for the gold bath. A black es in the "Journal" as to the most up-to-date manner of ucting a large business in town, with reception-rooms and ous studios furnished in the most luxurious manner, but all s of very little use to him with his small studio and only one ant, the last named being, perhaps, only a boy. Such studios o be found in all country towns.

### The Studio Spring Clean.

at such a photographer must do in order to increase, as well ep, his business is to turn out better and more up-to-date and in order to do this effectively the first step will probably inaugurate a thorough "spring cleaning," giving the whole both inside and out, a good scrubbing in order to remove all etc., which may have accumulated. Some photographers are e habit of putting paint on the studio windows or whitening to keep out the sun or diffuse the light. If this is done it d always be on the outside, but a better plan is to hang a n of some light, thin material inside, which can be used or s circumstances ordain, and which is not only much more nient, but also gives a better appearance to the studio itself. again, these curtains will need to be renewed from time to and should never be allowed to present a dirty or faded rance, nor to hang in a slovenly manner. If a curtain rod t be obtained, ordinary blind cord is a good substitute, as it pulled quite tight without much trouble, and the rings of the n move over it much more easily than they do over wire, on,

salt bath may be substituted for the gold, giving a slightly browner black, but the results are all very similar, and we advise those of our readers who wish to obtain a black that no other process can equal to use the two baths as we have directed.

It may be imagined that this will unduly lengthen the process, but we must point out that in point of fact a print-out process is, in a medium-size business, much quicker and certainly more convenient than the other numerous papers in the hands of photo- graphers. Both platinum and carbon must be finished same day as printing, and this means, in the case of the former, at least half-an-hour, and in the latter at least an hour of personal attention, ir- respective of washing, however small the batch. With artificial light papers the quickness is more apparent than real, for only one nega- tive can be successfully printed at a time, and each print must be individually developed. With printing-out methods, however, a great number of frames can be printed together without waste, and the whole batch of one, two, or three hundred are easily toned together, even in the double bath, under two hours. Any period of time may elapse between printing and finishing.

There are one or two styles of prints that are very suitable for "Artista." Chief among these is the print masked out on to a large piece of paper and plate-marked. Previously, the emulsion remaining on the unprinted edges spoil the appearance of all but platinotypes.

The vellum grade of this paper stands entirely alone, and for high-class work is certain of a great vogue for the particular sheen and quality of vellum has always been desired. For Cosway border masks, for vignettes, for paper mounting, we should expect this grade to excel. It must, however, be treated with great care, as it very easily cracks if twisted at all. The thinnest grade of white, too, gets very pulpy and is easily torn towards the end of the process. It is, however, quite stout enough for small work, but for whole-plate and larger the thicker grades will be found more economical in use.

W. FOSTER BRIGHAM.

## A STRAIGHT TALK TO THE COUNTRY PROFESSIONAL.

the time of year when things are just about as quiet as they very well be the average country photographer finds time hang ily on his hands, and begins to wonder how matters can be o to look a little brighter. Trade has not been as good as it t have been, and something must be done, but what? He has eeling that business that used to come to him is now going him, he conducts his business on the same lines as he has ys done, yet is not doing the same amount of work. He reads es in the "Journal" as to the most up-to-date manner of ucting a large business in town, with reception-rooms and ous studios furnished in the most luxurious manner, but all s of very little use to him with his small studio and only one ant, the last named being, perhaps, only a boy. Such studios o be found in all country towns.

which latter they are apt to grip, especially when it has been in use some time.

A very important item in the arrangement of a studio is the condition of the walls, which should either be painted in a quiet colour or covered with canvas of a dull shade. In the latter case they might be divided into panels with strips of thin wood, such as is frequently done at exhibitions. The main thing, however, to be remembered is that everything must be subdued in colour and in good taste. A few well-chosen examples of the photographer's work, suitably framed, will give a pleasing and decorative effect to the whole.

Do not crowd the studio with accessories, have as few as possible, and keep them out of sight till they are needed for use. A studio should look as much as possible like a room, not a workshop, and there should be no litter of odds and ends lying about. A few well-chosen backgrounds should be at hand for use when required, together with a good length of art serge of a dull shade, which makes a very serviceable background for photographing groups. All specimens should be kept in either the reception-room or the shop, and these should be frequently changed and never on any account allowed to show signs of dust or age.

### A Standard of Good Work.

All work sent out should be the best of which the photographer is capable, and must never show any sign of haste or carelessness. In addition to the ordinary and most usual style of photograph, which can be produced at a popular price, the photographer should make a specialty of one of the more expensive processes, such as platinotype or carbon, and be prepared to supply prints of the best quality in that process, for which, of course, good prices must be charged. A photographer who desires to keep his business up to date and yet cater for sitters who have not yet reached the heights of platinotype or carbon, or, it may be, cannot afford to pay the

prices which such processes demand, may still be educated to something better than the old-fashioned and highly glazed P.O.P., which some persons, even now, think the only correct medium. There are other papers and processes at the photographer's command which can be produced quite as cheaply, but which will considerably raise the status of his work. If sitters are only shown specimens of high-class work, and it is taken for granted that they want the best, they will accept it as the right thing, and the photographer may thus do a high-class business, though he may only have a small studio in a small country town, and at the same time cultivate the taste of his sitters for something better than they have hitherto been accustomed to. One very important item, also, to remember is—never to let any photographs ordered be in any way inferior to the specimens shown to the sitter at the time the order was given, for if this should happen the photographer's reputation will suffer considerably. Also, never try to pass off anything inferior to that ordered because it is less trouble, or takes less time, such as passing off photographs on gaslight papers for platinotypes; such a course is fatal to success. Bromide paper is a very good second to platinotype, and if care is used to get a good colour in development, followed by thorough fixing and washing, good work can be turned out in this process, and supplied at a considerably cheaper rate than platinotype. Gaslight papers can also be frequently used to advantage, but are not so permanent as bromide, and permanency of the prints is a very important factor in the professional photographer's work, as if a portrait soon fades, or shows signs of discoloration, his reputation is sure to suffer.

#### Rapid Printing of Bromides.

If much printing in bromide or gaslight papers has to be done some kind of printing-box should be made, so that a number can be printed from the same negative on one large sheet of paper, which does not involve the same risk of damaging the negative as when one is constantly opening and closing a printing frame and taking out one piece of paper and putting in another, often

probably with wet fingers. With a printing-box, after finding the correct exposure, one has only to expose as many times as the sheet will hold, and then, as the correct exposure has been obtained, it can be developed at once, taken from the developer at the same time, and transferred to the hypo, with the result that the whole are finished in a comparatively short time. The printing-box may be quite a simple affair, all that is required being a large box with an opening cut in the centre to hold the negative and room inside for a good light, either a gas bracket or a lamp. A strip of white paper is pasted along the top, marked off to the required size, the paper laid on the negative at one corner, and the two brought into contact by placing a suitable weight (such as the back of a printing frame) on top. The exposure is made by turning up the gas or by the removal of a sliding door or flap placed under the negative, and as each print is correctly exposed the paper is moved the right width of the picture along the mark on the white strip, and this is continued until the whole sheet has been exposed. The prints may be either in long bands or another set of guide marks can be provided and the paper moved up the length of the negative. This is the best and easiest way of printing bromides, and there is much less handling of the paper than when it is in small pieces.

During the summer months some kind of printing-out paper will probably be used, and care should be taken to select a good brand of collodio-chloride matt paper suitable for the platinum bath. This requires some little care in handling, and should be kept flat all the time in the various baths. Use large dishes and wash between each operation, and in the final washing each separate piece of paper should be handled several times, draining, washing, and re draining, but always kept flat.

By constant attention to details, both in connection with the studio and the practical part of the work, a photographer can not only keep up his business, but considerably improve it, and make good reputation for himself, not only in his own immediate neighbourhood, but probably beyond it.

J. PEAT MILLAR.

## THE POSING OF LADIES.

[Every photographer is bound to become very largely a law unto himself in the matter of making portraits of women, and it is doubtful if any set of rules, however good, can be of material benefit to the portraitist who is really bent on excelling in his work. However, the following notes, which appear in "The Professional and Amateur Photographer," contain a good deal which may be studied with profit by those less proficient in the art of portraiture.—EDS. "B.J."]

UNDOUBTEDLY, the source of greatest revenue to the photographer is the making of pictures for and of the ladies. He not only makes pictures of them, but through their influence makes pictures of others. It is through their influence we make the pictures of the children. If the having pictures made of the little tots was left to the man of the house, I very much fear we photographers would have to go out of business in short order. Mother wants some other mother or friend to see what a wonderful child she has, and of course the way to show off the good looks of the little one is to have her picture made. As a rule, we are all glad of the opportunity to make pictures of the ladies. I say as a rule, for of course we have an exception to this rule in our friend Pirie McDonald. It is much easier to pose the ladies than it is the gentlemen, for the reason that they possess a natural grace no man can or should possess. In addition to this natural grace, the dress aids one in securing graceful lines and curves. The dress of the gentleman is in straight lines, from the top of his head to his feet, so that it is almost impossible to produce curves. The best one can do as a general thing is to "break" these lines by having them take another direction, or introducing a second line, to break up the general direction of the first. In posing the ladies this is seldom necessary, as the outlines of the figure are curves, and the dress is usually so made that all of the inner lines are really curves. Where curves predominate, we seldom find a pose that is not pleasing. Often we hear the complaint made by an operator that his subjects are not what they should be for making pleasing positions of them. As a rule, this complaint is made by a man who does not really understand the art of posing.

**Pose by Suggestion.**  
The most pleasing effects in portraiture are those which the position suggests naturalness and not posing. When a picture shows a pose that gives the impression that the operator had some trouble in getting it, that picture lacks just that much being an artistic result. Naturalness is a total lack of posing. The most successful operators are those who pose their subjects so that they do not show they have been posed. Many an operator says he does not pose his subjects at all, simply allowing them to fall into a good, easy position of their own accord. This may sound well, but is not literally true, for that operator waits until they do fall into a good pose, or he moves his camera to a point where all the lines are broken up, or the lines really become curves. He may actually take hold of his subjects and turn or twist them about until the position he wants is secured, but by a sort of suggestion (not hypnotism) he aids his subjects in falling into a good pose, that after all he really does do a certain amount of posing. When one can manage his subjects in this way it is better than "handling" them under the light. If he wants the head turned a trifle from the light, or slightly "tilted" to one side, and secure the desired end by suggesting it to the subject, and she or he follows the suggestion, it will give a naturalness to the pose that is far ahead of the pose secured by actually taking hold of the subject's head, giving it a twist or a screw to get that effect. It is usually easier to suggest the pose to a lady. It is part of a lady's life to pose. She makes it her business to look pretty at all times, if possible. She does so, and is more willing to aid the operator in securing a certain pose than is the man. Every subject has some little individual

trick in posing, and the shrewd operator soon detects this little bit or trick; she may carry her head a little to one side, and the operator who understands his business will try to preserve this little individuality, not as a deformity, but rather he turns it into a "catchy" little tilt of the head, very attractive. One should never try to pose all of his subjects after a pattern. This is too often done. It is many have a preconceived pose, and try to mould all of his subjects into that pose. It is very much like the old-time monks' cell. When they had an applicant to join their monkish ranks, one of the old monks would go out and lay down in the sand and roll over. He would then have the applicant lay down in the hole he had made, and if the applicant was too short he was stretched to the mould; if he was too small, he was widened out until he fitted the mould—all individuality being buried. The operator should never fall into this deplorable habit, for he not only kills the individuality of his subject but his own as well.

### Some Maxims in Posing.

The posing chair used by the operator should be one that revolves, for often by simply having the subjects turn from side to side on the chair, all lines are altered, and what is from one point of view a very bad pose may from another point be a very attractive pose. A chair of this kind also saves much changing of the subject, and the operator can do his work in a more expeditious manner, thus avoiding all annoyance to the subject. There are, of course, a few general rules that may be applied to all subjects. It is to have the head turned slightly in an opposite direction to the body. For example, if the subject's body is turned slightly away from the light, the head should be turned back a trifle towards the light. This prevents a "sameness" or monotonous effect in the work. To have the head and body facing in the same general direction shows that the subject was having her picture taken. That is just the effect we do not want to see. If her body is turned towards the light her head should be turned back a trifle away from the light. The eyes should, as a rule, be turned a trifle further towards the head, and should always be turned in the same direction as the head is turned. Where the suggestions as to the pose of the body and head are followed we secure what has been called the "S" or the serpentine pose, which contains all the curves. This pose makes it possible for one to start a line at the top of the subject's head, and, running around the outline of the head on the left side down the face, under the chin, and outward on the left shoulder, forms the letter "S." Or we can start the line at the top of the head, and, running around the outline of the head on the right side of the face, under the chin, and outward on the right shoulder, form the letter "S" again, only this time it is "backwards." This is posing in curves, or forming "S" curves, as it is sometimes called. Where this plan of posing is followed, it will give all of the inner lines as curves, or "S" curves, in such a manner they will not attract too much attention for their weight. Not only should this plan be followed in posing the subject for "bust" work, but should be for three-quarter and full figures. To aid one in securing this effect in the full figure work it is best to have the lady subject set the foot nearest the camera forward, and throw her whole weight forward on that foot. This gives the long sweep to the dress, so much desired. It prevents the dress from falling about the limbs, and keeps up about the subject's feet.

FELIX RAYMER.

**INTERIOR COMPETITION.**—The Birmingham Photographic Competition announce results as follows: 1st prize of one guinea.—Rev. J. Clarke, Washfield Rectory, Tiverton, Devon. 2nd prize of £6.—Mr. H. Clarke, Stockport. 3rd prize of 5s.—Mr. P. W. Bushey, Herts. Twenty consolation prizes as follows: Mr. J. Ham, Redditch; Mr. J. Horton, Birmingham; Miss A. Stammers, Tewkesbury; Mr. Stimson, Portsmouth; Mr. G. T. on, Manchester; Mr. Duxbury, Blackburn; Mr. Cheetham, Birmingham; Mr. J. Maddison, Middlesbrough; Mr. Neville Aveling, Herts; Mr. S. Pugh, London; Mr. J. W. Whaley, Scarborough; Captain Bunbury, London; Mr. Gunton, Watford; Mr. Burnley; Mr. J. Thresh, Bridlington; Mr. M. S. Smith, London; Mr. J. Stott, Oldham; Mr. Ferguson, Birkenhead; Mr. J. R. Reading; Miss Howe, Norfolk.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were received between April 21 and 25:—

**CINEMATOGRAPHS.**—No. 8,758. Improvements in machines for projecting cinematograph pictures. Vincent Edward Horsman, Cratfield, Grove Road, Wallasey, Cheshire.

**PLATES.**—No. 8,875. Improvements in or relating to photographic plates or films. Max Hansen, 256, Portland Road, South Norwood, London.

**COLOUR PHOTOGRAPHY.**—No. 8,949. Method for photographic and photo-mechanical reproducing three or more coloured pictures. Richard Merkel, 116, High Holborn, London.

**CINEMATOGRAPHS.**—No. 8,963. Improvements in or relating to means for displaying animated pictures or the like. Frederick De Mare, 72, Cannon Street, London.

**COLOUR-SCREEN.**—No. 9,044. Method of manufacturing colour-screens for photography. George Sydney Whitfield, St. Albans road, Watford, Herts.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**CAMERAS.**—No. 14,916, 1907. The invention relates to a means for automatically fixing the struts which support the lens front of a folding camera in such a manner that their slots form a track parallel to the focal plane when the camera is opened, thereby ensuring perfect parallelism between the front and back of camera. This is done by means of a rocking plate pivoted to the lower part

Fig. 1.

of one of the struts on each side of camera. The rocking plate is provided with a pin or lug which springs into a recess formed on the suitably curved edge of the bracket when the strut is raised to the upright position.

To obtain free movement of the struts the rocking plates are pressed out of gear with the brackets, when their springs throw them over the dead centre and retain them thus until they are pressed back either by the fingers or the action of closing the camera.

In the latter case they are returned to the operative position by projecting parts coming into contact with the baseboard. The

springs connected to the rocking plates operating on either side of the dead centre it follows that they are effective in holding the pins or lugs on the plates either in or out of gear with the recesses in the brackets. Suitable stops are provided to limit the movement of plates in both directions. The main advantage of this improvement is that free movement of the camera front can be obtained at will, and the upright position of the struts is ensured when the camera is set up.

To a bracket 1 fixed to the baseboard 9<sup>a</sup> of camera are pivotted struts 2 and 3, in the slots of which run the usual threaded pins that support the front, the pins being furnished with clamping heads 4. At 5 is pivotted a rocking plate 6 provided with a stud 7 which is caused to spring into the notches 7<sup>a</sup> or 7<sup>b</sup>, formed on the edge of the bracket by the thrust of the spring 8. When the rocking plates are pressed backwards, as shown by the dotted

Fig. 2.

lines fig. 1, they are held out of gear with the notches, and the struts may freely swing in the backward or forward direction. In closing the camera, the rocking plates are thrown out of gear with the brackets, and as the struts arrive at a position approximately parallel with the base, as in fig. 2, the end 9 of rocking plate, making contact with the base 9<sup>a</sup>, causes the plates to spring to the operative position, the spring 8 operating on either side of the dead centre represented by a line projected from the stud 10, on which the spring turns, to the pivot 5 of rocking plate. When opening the camera the stud 7 strikes the rounded edge 11 of bracket and springs automatically into the notch 7<sup>a</sup> when the strut 3 arrives at the upright position. The bolt 12 on the lower part of the front board may then be placed in gear with the slot and the front raised or lowered in the usual manner.

When it is desired to extend the camera to its greatest limit the struts are swung forward so that they overhang the front edge of baseboard, the rocking plates being placed out of gear with the notches 7<sup>a</sup> and in gear with the notches 7<sup>b</sup>, in which position the struts are held at a uniform angle to each other on either side of camera and the front is adjusted to the upright position by swinging it on its supporting pins, the bolt 12 being out of action to allow of this movement. It will be understood that although only one bracket and its necessary fittings have been described, each camera would be furnished with two, one on each side of the baseboard. Herbert Holmes, Ensign Works, Clifford Road, Walthamstow; William Albert Edwards, Ulverston Road, Walthamstow; and Houghtons Ltd., 88-89, High Holborn, London, W.C.

The following complete specification, etc., is open to public inspection under the Patents Act, 1901:—

CINEMATOGRAPH.—No. 8,542. Uninflamable film for cinematograph and a process of manufacture of same. De Briaillies.

### New Trade Names.

TRIANTRENE.—No. 299,732. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Society of Chemical Industry in Basle, 151, Klybeckstrasse, Basle, Switzerland, chemical manufacturers. January 18, 1908.

WELDITE.—No. 300,479. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Thermit, Ltd., 27, St. Martin's Lane, Cannon Street, London, E.C., manufacturers. February 14, 1908.

SOLVOS.—No. 300,758. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Arthur Ross, Hotchkiss, and Co., Ltd., 1, Glengall Road, Old Kent Road, London, S.E., manufacturers. February 25, 1908.

MILBAR.—No. 301,360. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Beharell and Son, London Road, Barking, Essex, paint and varnish manufacturers. March 16, 1908.

## Analecta.

### Spirit Sensitisers for "Oil" Printing.

I should like (writes Mr. S. L. Coulthurst in "The Amateur Photographer") to recommend to those readers who are beginners in "oil" printing not to make up their own sensitisers, but to straightway buy a bottle ready prepared. With a bottle of "spirit sensitiser" the Autotype Company send out a coating brush; it is a good, old-fashioned brush, which may be new to many present-day pictorial workers; it is what is known as a "Blanchard's brush." It consists of a piece of glass, say half-plate size, cut down the centre, and making a piece  $\frac{1}{2}$  by 2 $\frac{1}{4}$ , or thereabouts; then a piece of swan's-down calico or fluffless flannelette is wrapped over it, and fastened to the glass by a rubber band. It is one of the best brushes that can be used. In place of the glass a piece of thick celluloid may be used, and this will give the brush somewhat of a spring.

Now, to coat my paper for "oil" work I go into the dark-room and take a clean quarter-plate dish which is quite dry, tilt it up one end, and pour into it a small quantity of the spirit sensitiser—say, about an ounce for four 12 by 10 pieces of paper; more or less solution should be used according to the quantity of paper that is to be coated.

Next take a piece of blotting-paper, and put this on a board piece of glass, or other such article, and with the aid of two glass-headed pins fasten the piece of paper to be sensitised at the top; now dip the "Blanchard's" brush into the quarter-plate dish with solution, and take up as much as the brush will carry, and go rapidly over the paper from top to bottom. The brush will coat it quite smooth and even. It will start drying almost before you can take it off your board. I have a large hinged box which line with blotting-paper top and bottom. When No. 1 piece is coated, I put it into the box, and go on with No. 2, and so on until all are ready; then I pin them, some on the lid of the box and some on the bottom of the box, and shut it up. The whole are dry in about ten minutes or less. Now, to make the paper almost "bone-dry," I take the box and put it in the oven top in the cooking-range, and the whole is then in fine condition for work. In damp weather paper dried in an ordinary room will have a limp feel unless the room be warm; if limp, it does not work so satisfactorily.

By employing the method of working above described I have, during the damp months of the year sensitised, dried, printed, and had the print in the washing water inside one hour.

## New Books.

THE ROYAL GARDENS, KEW.—An excellent illustrated guide to the gardens and plant houses of Kew has been issued by Mr. E. Wallis, photographer, 42, Gloucester Road, Kew Green, S.W., whose numerous photographs are added descriptive notes of the plants and gardens by Mr. Herman Spooner. Mr. Wallis' photographs provide an excellent souvenir of the Royal Botanic Gardens, and the book is certainly the best and most informative of the publications we know relating to Royal Kew. It is published in 1s. and 2s. 6d.

NOTICE OF REMOVAL.—MESSRS. E. Osborne and Co., the well-known firm of photographic mount manufacturers, have removed to new premises, known as "Red Lion Works," Warple Way, Acton, W., which address all communications should now be sent. Messrs. Osborne also advise us that samples of photographic mounts will be sent free to any professional photographer applying for same.

## New Apparatus, &c.

"Lightning" Bromide Printer. Made by J. E. Daniel, 35, Stockton Street, Manchester.

This piece of apparatus just introduced for the rapid production of slide and gaslight postcards has certain claims to notice which

by us giving a description, after close inspection of it, for the benefit of our readers. The printer consists of a chamber measuring 12 1/2 in. by 18 in. by about 20 in. high, which is fitted with a light-tight lid, and contains either an incandescent gas lamp or an incandescent electric light. The ends of the printer are provided with carriers for taking either a half-plate or quarter-plate negative. The carriers are placed against apertures in the end wall of the printer, and are each covered on the inside with a ruby window working in a pair of runners. The apparatus thus offers the advantage

allowing two workers to use it at once independently of each other, the exposure being made simply by lowering the ruby window, which is done by pulling out the knob, seen in the lower part of the drawings. The metal spring raises the window on the end of the carrier and finishes the exposure. It will thus be seen that the printer allows of the negative being seen at the time the exposure is being inserted, whilst the use of the apparatus by two workers using only one lamp is certainly an economical point in its favor. The prices of the "Lightning" printer, complete with lamp and gas fitting for attachment to any electric fitting, is 50s. For incandescent gas light the price is 52s. 6d.

## New Materials, &c.

ENLARGING WORK.—Messrs. A. King and Co., The Studio, High Street, Littlehampton, send us examples of the cheaper class of enlarging done by them for professional photographers. While not intending to compete with the higher classes of enlarging, the prints are nevertheless of a kind which should certainly find a market with those supplying the lower middle classes. An example of the work will suffice to show Messrs. King's prices:—12 x 10 enlargement worked up, 2s., sepia toned 2s. 3d. Other grades of work are also offered, and are evidently turned out with care. The firm, which makes a specialty of prompt work, is also prepared to quote for finishing, etc., at clients' own

## CATALOGUES AND TRADE NOTICES.

THE CAMERA CONSTRUCTION COMPANY.—A new 1908 list of their stand cameras reaches us from this firm, and will be sent post free on application to Eagle Works, Durham Grove, Hackney, N.E. The company offers some remarkably good value in half-plate and other sets.

"YESTERDAY AND TO-DAY."—As interesting a piece of free photographic literature as any we can remember is that just issued by Messrs. Burroughs, Wellcome, and Co. under this title, "Yesterday" being the dark age before the arrival of "tabloid" compressed photographic chemicals, though presumably the suggestion of the cover, that one must go back to the Pharaohs to reach this period, is not one to be taken seriously. But what may be taken very seriously indeed is Messrs. Burroughs, Wellcome's aim, and, we can add, accomplishment, to provide the photographer with all his needed solutions in the minimum of space and the maximum of printing. We suppose no old-time lover of solution-mixing is with us still, but must confess to taking advantage of the "tabloid" method every now and then, whilst a good many of us are confirmed in it as a habit of which we have no desire to break ourselves. Both classes can hardly fail to read with interest the "Yesterday and To-day," which is offered them free from Snow Hill Buildings, E.C.

MR. LIZARS' PRICE LIST.—The 1908 edition of this list is a handsome volume of over 200 pages, describing a very representative assortment of the best appliances, many of them to be obtained only from Mr. Lizars. The section devoted to hints and formulae, which is a feature of the price list, bears evident signs of recent revision. It

gives the instructions for carbograph and oil printing, and there is a special chapter devoted to the Autochrome process. One novel idea we must mention—viz., the use made by Mr. Lizars of the "B.J. Almanac," to illustrate the small dimensions of one of his cameras, the "Challenge Dainty Pocket." The list itself is sent free on application to 101-107, Buchanan Street, Glasgow.

"THE PROFESSIONAL PHOTOGRAPHER."—No. 10, of Vol. I., of the Kodak Company's monthly professional organ contains articles on Velox and child portraiture, with particulars of the Kodak Company's new introductions in the way of backgrounds, mounts, and studio furniture.

VOIGTLANDER CAMERAS AND LENSES.—A list of their latest models of cameras reaches us from the firm of Voigtländer, 2, Charterhouse Street, E.C., and is to be warmly recommended to those about to purchase a hand camera, since it describes in detail with regard to practical conditions the various patterns of instruments manufactured by the famous Brunswick firm. We are glad to see Messrs. Voigtländer emphasise the 3 1/4 x 2 1/4 size of their excellent reflex, but this type of camera is, of course, not the only one they issue. The folding focal-plane, of both the strut and baseboard type, is represented

by two excellent cameras, while those who must have the smallest bulk can choose the double extension, yet highly portable "Alpine." The list also specifies the Voigtlander lenses, and should certainly be in the hands of any who require apparatus of the best workmanship.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, MAY 9.

United Stereoscopic Society. Outing to Chislehurst.  
North Middlesex Photographic Society. Outing to Dartford.  
Handsworth Photographic Society. Excursion to Solihull.  
Hackney Photographic Society. Excursion to Kew Gardens.

MONDAY, MAY 11.

Gravesend and District Photographic Society. "Field Work." J. T. Dalladay.

TUESDAY, MAY 12.

Royal Photographic Society. Opening of a One-man Exhibition, by Furley Lewis, with an Address. A Demonstration of a New Process of Printing in Monochrome by Imbibition. Frank Donisthorpe.  
Manchester Amateur Photographic Society. "Individuality in Art." T. Longworth Cooper.  
Wimbledon and District Camera Club. "The Romantic in Landscape." F. C. Tilney.  
Hackney Photographic Society. "Oil Process." H. W. Lane, S. W. Morrison, Wm. Rawlings, and F. E. Roope.

WEDNESDAY, MAY 13.

Croydon Camera Club. "The Theory and Practice of Time Development." W. F. Slater.  
Central Technical College Photographic Society. "Toning Bromide Prints." R. Hudson-Spence.  
North Middlesex Photographic Society. "Ten Minutes' Papers." E. A. Morgan and H. W. Fincham.

THURSDAY, MAY 14.

Chelsea and District Photographic Society. Affiliated Competition Slides, 1908.  
Richmond Camera Club. General Meeting.  
Handsworth Photographic Society. "Wood-engraving and Electrotyping." A. E. Cope and A. A. Major.  
Southend-on-Sea Photographic Society. "Criticism of Exhibition Pictures." A. J. Conaaber.  
Hackney Photographic Society. Excursion to Leigh and Benfleet.  
London and Provincial Photographic Association. "Afar in the Fatherland." W. L. F. Wastell.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held May 5, the President, Mr. J. C. S. Mummery, in the chair.

Mr. Leslie Clift gave a lecture-demonstration of half-tone block-making, in the course of which he showed and explained the stages of making a half-tone photo-engraved plate. He laid particular stress on the cleaning of the glass for the wet collodion negative, recommending a weak solution of iodine in alcohol for the purpose. In the matter of originals, he put a good gaslight print first, next P.O.P. properly toned, not double toned, and last in favour carbon, gum and oil.

CROYDON CAMERA CLUB.—A lecture on "Photographic Shutters" was given by Mr. E. A. Salt last week, the theory underlying shutters in general and the characteristics of various forms being fully considered. From the nature of the subject it is impossible to epitomise it. The lecturer also exhibited an apparatus of his own design for testing the "speed" of shutters and recording their efficiency. Since its completion he had ascertained it could only be held to be a modification and simplification of an apparatus designed long ago by Sir William Abney. In the device shown the image of a slit illuminated by an incandescent gas mantle—the slit being at right angles to the travel of the shutter—is focussed by a lens on a dry plate, rotated horizontally at constant speed by means of a motor. A surface-silvered mirror at an angle of 45 degrees enables this to be done. The lens is mounted in a sliding tube for adjustment, and with the mirror, dry plate, and motor, which are in a light-tight box, form one part of the appliance; the carrier for the slit and illuminant forms the other. Lens front and slit both rise and centre to permit several diagrams on one plate, the highest speeds being taken at the circumference to obtain wider readings. A glass protractor (made by copying in the camera) is applied to the developed plate, and "speeds" read off direct in fractions of a second, the width of the image of the slit being allowed for. The number of degrees occupied by the opening and closing of the shutter and those comprised in the period of full aperture are also noted, and a diagram made therefrom on squared paper. The "efficiency" can then be

obtained by the simple expedient of counting the number of squares occupied by the diagram of the shutter tested as compared with the number of squares representing the hypothetical ideal shutter. The whole apparatus is of a portable nature, and the readings given by it are very clear and distinct. An animated discussion followed, at the close of which Dr. Mees, in proposing a vote of thanks, said Mr. Salt had dealt with an important subject in a very thorough manner. Very little in this country had been written about the theory of shutters, and many of the points raised were most interesting. He trusted the lecturer would publish the paper.

WORTHING CAMERA CLUB.—The annual meeting of the Worthing Camera Club was held recently at the Music Studio, Liverpool Terrace, the president (Dr. W. Ayton Gostling) presiding over a fair attendance of members. The committee's report stated that the members numbered 74, against 68 last year. The accounts revealed a balance in hand of £18 17s. 6d., and the assets of the club were valued at £25 10s. Dr. Gostling was re-elected president, and Mr. F. Hinds and Mr. T. H. Crouch were added to the vice-presidents. Mr. Edmund F. H. Crouch was re-elected hon. secretary, Mr. R. Long hon. treasurer, and Mr. L. Knight was appointed assistant hon. secretary. Messrs. A. C. Osborn, H. Swain, and W. H. Steel resigned their seats on the committee, and Messrs. P. Twine, R. J. MacDermott, and L. Knight were appointed to fill the vacancies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held April 30, Mr. O. S. Dawson in the chair. Mr. J. T. Butterfield gave a lecture on "Printing from Gelatine Surfaces"—viz., collotype—a subject in which he is the instructor at the L.C.C. School of Photo-engraving and Lithography, Bolt Court, E.C. He briefly described the process as follows:—

Two pieces of plate, or patent plate-glass, not less than  $\frac{1}{8}$  in. thick, are ground together with fine or flour emery powder (Oakley's "Wellington" knife polish is as good as anything), and a little water until an even matt surface is obtained. The surface of the glass is then coated with a preparation of beer and silicate of potash or soda and a few grains of tannic acid. This forms the substratum. When dry the plate is rinsed with filtered water and again dried and then placed in a drying oven on levelling screws, and heated to a temperature of from 100 to 120 deg. Fahr.; it is then coated with the sensitising solution, which consists of gelatine and a bichromate salt, and the temperature is raised to 140 deg. Fahr. When the plates are dry they are placed in the printing frame under a reversed negative and exposed to light.

After exposure the plate is developed in cold water, every particle of the bichromate salt is washed out of the film, and the plates are then stood in a drying rack and allowed to dry for about twenty-four hours.

At this point the lecturer passed round specimens of the glass, before and after grinding, coated with the beer solution, sensitised but before exposure, after exposure, exposed and developed, after damping and rolling up with fatty ink and ready for proofing.

Before printing, but after development, he continued, it was necessary to soak the plate in a mixture of water and glycerine for a short time. This is commonly termed etching the plate, but in reality it is simply swelling the gelatine, so that those portions struck by light will repel the greasy ink and allow only those parts that have been exposed to take the ink up.

The back is then cleaned to remove any stray particle of gelatine, the film blotted off with blotting-paper, and fixed to the bed of the printing press. A good nap roller, charged with stiff collotype ink, was next rolled over the plate, the screws and pressure bar adjusted, and a proof taken. Specimen prints were passed round, and was also in some cases the original drawing.

As to cost, the lecturer said that the glass worked out at about 6d. per 1,000 inches; further, the plates could be cleaned off and used again. The most expensive piece of apparatus required was the drying oven. The process itself was simple, but many failed owing to the surroundings not being suitable.

A good oven could be made by the amateur for his own use by adding an iron bottom to a square box, making two levelling bars with three screws, and heating underneath by the aid of gas rings, but hot-water pipes were the best for heating if they could be obtained, being more even in their action. Printing could be done on almost any press; in fact, the office copying press would, with care, turn out very fair results.

specimens of three-colour work by collogtype were passed round much admired, and in reply to a question as to which was the best press for the work the lecturer said that the scraper press was to be recommended.

The chairman said that it was stated that there was trouble in getting an even run of, say, 50 to 100 pulls, and Mr. Butterfield said that it all depended upon the printer; a good careful worker would not have the least trouble in getting even work.

Haddon asked what constituent of the beer did the trick in the first coating; all beers were not alike. Again, in regard to the use of calcium chloride, would not calcium chloride do for this in place of the oven, and, however carefully worked, would give a variation? The lecturer, in reply, said that he thought it was glucose in the beer that was the thing. Drying by calcium could be done, but it took a longer time and gave a coarser grain; in fact, it was a case of the higher temperature the finer the grain.

Haddon said: Why not use the glucose in place of the beer, as was this that was wanted? He also asked if it would be possible to combine heat and calcium together, so as to get exactly the result desired.

Asked by Mr. Burgess as to the number of prints that it was possible to obtain from one plate, the lecturer said that his highest was one of 4,000, but the life of a plate was generally reckoned at 1,000.

A vote of thanks brought the meeting to a close.

## Commercial & Legal Intelligence.

**ENLARGEMENT CASE.**—At the Scarborough County Court last before his Honour, Judge Dodd, K.C., Mr. Hart, solicitor, opened a case which came before the last Court in which the Judge gave a verdict for £6 to Mrs. Harriet Kemp, a widow, Durham, who sued the Great Britain Art Company, photographers, Grosvenor Street, All Saints', Manchester. Mr. Hart, appeared for the defendants, said that his Honour would remember that this was an action in which the plaintiff claimed £6 for the return of photographs, and damages for non-delivery of an enlargement. His Honour: Yes, I remember; it was the only photograph she had of her late husband.—Continuing, Mr. Hart said the representative of the defendant company did not arrive at Court until after the case had been heard, and his Honour then agreed that it should be opened at the next court if the £6 was paid into court that day. His Honour: I had thought that the whole thing was a fraud, and the representative made a statement which, if true, would show that was not so; and I thought it only fair that he should have an opportunity of showing me that the estimate formed on one was an improper one, and there should be a fresh trial.

Mr. Hart: We paid the full amount (£6) into court. The object of the defendant company in being present that day, continued Mr. Hart, was to give his Honour an opportunity of putting the matter to rest, for there was no doubt that the observations of his Honour at the last court were calculated to do the defendants harm. They were a firm in a very large way of business, and did many thousands of enlargements every year. Unfortunately the plaintiff's photographs and enlargements were by mistake sent on to Hull, and to every effort, it was not until after the last court that they were found. They have now been delivered to the plaintiff, who got everything she wanted. Mr. Hart was sure the Judge would be very first to allow him to put before the court evidence to show that, instead of being a fraudulent company, they were a perfectly sound and honest undertaking.

His Honour said he was glad to have heard what had been said, and that he gave the opportunity for the case to be reopened. They satisfied the good lady about the photographs, and now the case was closed. What the lady wanted was her dead husband's photographs back, and she had got it.

**"ART COMPANY'S" BANKRUPTCY.**—In the Salford Bankruptcy Court, Albert Fryer, carrying on business under the style of The Salford Zither Company, A. Fryer and Co., and the Fine Art Company, described as a dealer in photographs, has been granted a discharge, suspended for three years. Debtor carried on business

at Eccles, Chester, Manchester, Preston, and Blackburn. The reasons given in the order for not granting an absolute order of discharge were that the bankrupt's assets were not of a value equal to 10s. in the £; that he had omitted to keep proper books of account; that he had contracted debts without having at the time a reasonable ground of expectation of being able to pay them; and that he had contributed to his deficiency by gambling.

**LEGAL NOTICE.**—The trustee under the deed of assignment, executed by William Hallas, photographer and framer, 73, Market Street, Stalybridge, announces that claims against the estate should be sent by May 30 to Mr. Harry Thorp (of Heap, Son, and Norman), 129, Stamford Street, Stalybridge, accountant.

**PARTNERSHIPS.**—The partnership between John James Askew and Henry Richard Dodd, photographers, carrying on business at 40 and 42, Broad Street, Hanley, Staffs, as Askew and Dodd, has been dissolved by mutual consent, and all debts will be received or paid by J. J. Askew, who will continue the business in his own name.

The partnership between Samuel Wilson Bird Jack, and David Hay Jack, photographic artists, of 19, Lowther Street, Carlisle, has been dissolved by mutual consent, and all debts will be received or paid by S. W. B. Jack, who will continue to carry on the business.

### NEW COMPANIES.

**NAYLOR AND CO., LIMITED.**—Registered April 16. Capital £1,500, in £1 shares (500 preference). Objects: To acquire the business and assets of T. C. Naylor, of 24, Denmark Street, W.C., and 4, Roscoe Street, E.C., and to carry on the business of manufacturers of photographic apparatus, machine-made boxes, process studio and scientific work, etc. No initial public issue. Registered office, 24, Denmark Street, Charing Cross Road, W.C.

**WORLD'S GRAPHIC PRESS.**—Capital, £3,000 (£1).—To take over the business of a photographer of topical and other events and vendor of photographs to the press of the world carried on by F. da Paul Romani at 44-46, Fetter Lane, E.C., as the "World's Graphic Press," and to adopt an agreement with the said vendor and C. C. Barker for the acquisition of the inventions relating to therein.

## News and Notes.

**PERSONAL.**—We regret to announce that Prof. G. Lippmann is seriously ill with pneumonia, following on an attack of influenza.

**"KINEMATOGRAPHY."**—A comprehensive treatise on the cinematograph under this title is in course of preparation by Mr. Theodore Brown. It is to be issued at 7s. 6d., and orders for it may already be sent to the author at 22, Gresham Road, Brixton, S.W.

**RECEPTION-ROOM PROBLEMS, No. 1.**—She asked him if he was the photographer. He said he was.

She asked him if he took children's pictures. He said he did.

She asked him how much he charged. He said: "Four dollars a dozen."

"Then I'll have to go somewhere else," she replied; "I only have eleven."

**THE KODAK IN SOUTH AFRICA.**—During the past few months representatives of Kodak, Limited, have been busily engaged in South Africa bringing home to the people of the Cape, Natal, the Transvaal, the Orange River Colony, and northwards as far as the Victoria Falls the features of the Kodak system, which have made photography at once so easy and so fascinating. As may be supposed, the Kodak Company relied very largely upon public exhibitions of a splendid collection of enlargements as the centre of attraction, supplementing these with frequent demonstrations of the simple and commendable daylight system of development made possible by the Kodak developing machines. All the pictures shown were enlarged upon Kodak bromide papers from Kodak N.C. film negatives, which illustrated in a conclusive way the efficiency and the possibilities of the Kodak cameras, from the 5s. Brownie to the fully-equipped folding pocket and cartridge Kodaks.

The South African papers report at length upon the keen interest which these exhibitions have excited amongst amateur and pro-

fessional workers, such a fine collection of photographic pictures having never been seen in this part of the world. The exhibitions and demonstrations have been speaking testimony to the good qualities which we have learned to associate with Kodak manufactures, and deservedly attracted much attention, putting in a new light to a large number a process of picture-making hitherto associated with hours spent in the dark-room, but now carried out entirely in daylight. There should follow a great increase in photographic activity in South Africa, where the opportunities of picture-making are many and varied, and the Kodak Company may expect, and will doubtless experience, a large extension of business as the result of their enterprise.

REPRODUCTIONS OF ART MASTERPIECES.—With the immense number of reproductions of pictures in the three-colour process which have flooded the book-shops and picture-framers recently, the almost total neglect of lithography for reproductive purposes is often remarked. Messrs. Arnold Fairbairns and Co., Ltd., believe that a popular appreciation of such work exists, however, and are preparing to meet it with a series of lithographic reproductions of great masterpieces. The first subject, Burne-Jones' "Golden Stairs," will be published on the 11th inst., in a size that fits it for framing, being one-eighth of the original. This choice of subject is particularly interesting, as the picture will be shown at the Franco-British Exhibition, its first appearance in a public gallery since the Burne-Jones memorial exhibition at the New Gallery. Other subjects are to follow, each in a separate portfolio at one shilling net, the series being known as "Masterpieces."

THE PHOTOGRAPHIC SURVEY AND RECORD OF SURREY has just issued its sixth annual report, which shows that good progress has been made during the past year in the many branches of "record" work undertaken by the association. At the annual meeting Sir Benjamin Stone gave an address containing much useful and helpful information for all interested in this branch of photographic work. Any desirous of becoming members of such an association should communicate with the hon. secretary, Mr. Frank F. Wood, 11, Milton Road, Wallington, who will furnish all needful information.

PHOTOGRAPHIC RECORD AND SURVEY OF SUSSEX.—This association, which has recently been reorganised, has just issued its annual report for 1907, the balance sheet of which shows a surplus on the right side of the ledger. Although the membership roll has considerably increased there are doubtless many who do not know of the association, and these would do well to communicate with the hon. secretary, Mr. L. A. Gilbert, Public Library, Brighton, who will gladly forward all information as to the aims and objects of the society.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE PORTRAIT POSTCARD

To the Editors.

Gentlemen,—After 40 years' experience I have come to the conclusion that photographers as a class are commercially the most short-sighted men in business. They are entirely without "esprit de corps," and deficient in pluck and backbone. Twenty years ago photography was a pleasant profession, and fair incomes were made. The British public was quite content, and paid well for good work. Then—without any demand on the part of the British public—the average photographer commenced a pleasing game of "beggar my neighbouring brother artist," cutting prices, and degrading a decent profession to a struggle for existence. As regards the postcard visitation, the solution is very simple. Let every man who charges 6s. or three guineas for a dozen cabinets steadily refuse to take less for portrait postcards. His clients will not object, and if some do, let them go. As for those who do 2s. 6d. or 3s. a dozen work, they will benefit the manufacturers for a short time; but will work hard to impoverish themselves in so doing. If they would only combine to keep up a fair standard price!—but this is past praying for.

There has never been any etiquette in the conduct of the majority of studios, and the result is, photography is no longer a career that I should advise any ambitious young man to go in for. It has been spoiled by the very men whose interest it was to enable them to make a decent living.—Yours truly,

W. I. H.  
14, Moor Mead Road, St. Margaret's, Twickenham.

To the Editors.

Gentlemen,—I do not know that "Fair Trade and Fair Prices" last effusion calls for any reply from me. I can very well see he is not the kind of person to be dethroned from his pedestal of righteousness. Anyway, I do not feel inclined to satisfy his morbid curiosity as to my prices or system of working.

His dogmatic assertions as to "Arch Fiend's" methods and chimerical views in general of the outdoor worker are nothing but the outcome of "swelled head," which he is acutely suffering from. Quite one-half of the "velveted" photographers have no idea whatever of our manner or mode of conducting business. That occasional "shark" is rightly brought to book no more condemn the whole outdoor workers than a bad penny spoils the Mint. "The solitary champion" of the "touters," I am not afraid to assert that we look with supreme contempt on "F.T. and F.P." and all of his kidney; and our indifference to their "dog-in-the-manger" attitude is only equalled by our determination to have "our" share of the "providence."—Yours, etc., ARCH FIEND

To the Editors.

Gentlemen,—Referring to the letters of late on the "Portrait Postcard," I do not wish to weary you with a long letter, but, summing things up, I think that if photographers of the past could but see the present "prices" and "style" of some "sweaters," would

A Spectre of the Past: "Alas!!! I am better off where I am."

not make them "turn" in their grave? What shall we see twenty years hence? One dozen photo-postcards of yourself given with every ½ lb. of tea. Autochrome stamp photos, 3d. per dozen, etc.—Yours faithfully,

A. CHANDLER  
"Readwood," Belgrave Road, Colwyn Bay, N. Wales.  
May 1, 1908.

To the Editors.

Gentlemen,—I think we have to look higher than the postcard fiend for the real culprit in the matter of the postcard nuisance. If the better-class men begin turning out good negatives, well touched, well posed and printed, full size (no margins) they will only themselves to thank if the postcards supersede cabinets. People do not buy a 6d. article for 3d. in any trade, and are quite capable of grasping this fact if pointed out. In my practice I always state this and tell a "postcard" sitter that it is "one position and no proofs," and that what are wanted must be ordered within a week of receipt of order, as the negatives are not stored. I neither varnish, retouch (or very slightly), nor name the negative.

s take an ordinary pose (no heads) small, and print with and I find cabinet work does not suffer.

inary cheap man does not take elaborate poses or large retouch, etc., and this is the man we have to fight. But 1-class man enters the lists—well, God help photography. Faithfully,  
PYRO AND SODA.

discussion is now closed. We refer to the correspondence on another page.—Eds., "B. J."]

## BLUENESS WITH AUTOCHROMES.

To the Editors.

en,—While reading through a contemporary periodical a o ago I came across a letter by Mr. H. T. Malby on the ect, in which he attributes the erroneous coloration to presence of white light in the dark-room during develop- is Autochrome plates, which entered through a defective and also beneath the door. Possibly my experiences relate- ness, or, as I perhaps may term it, blue fog, may be . Blue fog I have certainly obtained, but invariably aladjustment of the compensating screen, but never from which seems to have troubled Mr. Malby. He seems at fogging from blue light from the emulsion side is of blue fog, and this I most certainly question, for, in where my exposure has been in my opinion insufficient, ore the termination of the first development, diluted my with an equal quantity of water and then examined the ite light, and thus produced a superficial fog. This fog, or age, so to speak, of the white light has been entirely y solution C, and this has given me an appreciably more transparency at the finish, with very questionable deta- the colour rendering.

produced by white light acting *via* the starch grain screen s persist as a blue coloration, and when this occurs it hat its abolition seems hopeless. May I therefore suggest Malby possibly fogged his plates *via* the screen when dark slide, or perhaps permitted his screen to become through inadvertence during exposure?

also have obtained this blue fog if he develops his Auto- a glass dish if daylight enters his dark-room beneath the

s me that time development in his dark-room without n a porcelain dish would avoid this fog, even if daylight htly beneath the door, always supposing he is careful in dark slides and adjusting his screen.—Yours, etc.,

H. G. DRAKE-BROCKMAN, M.R.C.S.

ty Borough Asylum, Middlesbrough.  
1908.

k our correspondent has misread Mr. Malby's letter, not find in it any suggestion that light on the emul- n produce blue fog. Light entering under a door could e the glass side of the plate during transference either e slide or from slide to developing dish.—Eds. "B. J."]

ISTS' EXHIBITION.—Promoted by our enterprising con- "The British and Colonial Druggist," there is now open icultural Hall, Vincent Square, Westminster, S.W., an of the chemists' trades which has now become an annual event. Firms, large and small, in the chemical articles trade are represented, whilst the photographic chemist's business is represented by two firms only— ickyer, of Deptford, who shows a large variety of his parations, and Messrs. Theobald and Co., of Hounslow, all we saw one novelty in the shape of a very neat even-fold tripod which closes quite flat for travelling, in brass, 15s. 6d.; in aluminium, 23s. The stand hen closed, 11½ by 1½ by ¾ in., and opens to 49 in. Its brass is 22 oz.; in aluminium, 12 oz. The exhibition n until 10 p.m. to-night (Friday), and is worth a visit the object lesson in attractive stalls, and the tuneful "Bleu" Viennese orchestra, which, in the occasional or refreshment, is instantly replaced by a "White quartette.

## Answers to Correspondents.

\*<sup>a</sup> All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\*<sup>a</sup> Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*<sup>a</sup> Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\*<sup>a</sup> For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

F. J. Cawsey, 155, Chatsworth Road, Morecambe, Lancs. Photograph of H.M.S. "Akbar" Laying in Morecambe Harbour

F. G. Steggle, Stanley House, Midsomer Norton, near Bath. Photograph of Mr. and Mrs. R. Jones and their Ten Children.

A. Ross, Photographer, Evan Street, Stonehaven, N.B. Photograph of Capt. the Hon. A. C. Murray, M.P. for Kincardineshire.

J. Davison, 37, Poulton Road, Seacombe, Cheshire. Photograph of Harrowby (Seacombe) Amateur Football Club.

H. D. Wootton, 63, Albany Road, Redruth, Cornwall. Photograph of Clinton Road, Redruth. Photograph of Fore Street, R. druth.

CHEMICALS.—Will you kindly give me a formula for diamidophenol suitable for plates or paper? Also can you tell me what liquid bisulphite is?—HERBERT S. P. COSTER.

Potass. metabisulphite, 6 oz.; distilled water, 20 oz.; diamidophenol, 2 ozs. Dissolve and add gradually caustic soda or potash to dissolve the precipitate first formed. Dilute for use with 10 to 30 times the volume of water. The bisulphite is a strong solution.

PINATYPES FROM AUTOCHROMES.—Can quite satisfactory reproductions be obtained from Autochromes by means of pinatype? If so, could you inform me how to make the three-colour screens and approximate exposure ratio by daylight, or preferably incandescent gas, using Wratten's panchromatic plates for the negatives.—H. C. MILMAN.

See the article by M. Didier in the "Colour Photography" Supplement of last week.

COPYRIGHT.—If I purchase some local view postcards from a shop and they have not got "copyright" on them, am I allowed to make a negative of them, print same, and offer them for sale to shopkeepers, or must I take my own negative first?—AN OLD SUBSCRIBER.

Dear Old Subscriber. You cannot have read the repeated replies to queries such as this, or you would know that you have no more right to do what you suggest than you have to steal penny loaves from the baker's barrow. It is not necessary that copyright prints be so marked.

YOUNG PROFESSIONAL.—Bride and bridegroom in centre, with their respective parents beyond each; chief bridesmaid and "best" man to rear of bride and bridegroom respectively, with other bridesmaids grouped on either side. The guests come in at the back.

WOODEN TRAY.—I am making some large dishes for developing bromides, sides to be of wood, and glass bottoms. Can you tell me the best way to fix the glass in? Also what treatment the wood requires to make it impervious to the various chemicals used?—H. M. K.

Unless the wooden vessels are well made, and of well-seasoned wood, it will be next to impossible to render them permanently watertight. The bottom of the tray should be deeply rabbeted to take the glass which should be bedded in with a mixture of white and red lead. Then a narrow strip of wood is bradded on to further secure the glass, any intervening space being filled in with the lead mixture. Then asphaltum and beeswax, in about

equal parts, is melted and flowed over the inside, and the surface made even with a spatula, such as is used for spreading plasters. Several coatings of shellac varnish may be used in place of the asphaltum mixture, but the latter is better. We prefer wooden bottoms in preference to glass for wooden trays.

**PRINTS ON CELLULOID.**—1. Can you give me the outline of process used by celluloid printers known as "permanent photographic process"? 2. Can you suggest the best process for obtaining a black line reproduction (positive from positive) of a drawing (on paper) on celluloid. It is a large piece 33 in. x 9 in., so I want to get the cheapest possible process (without silver), and, if possible, without collodion or gelatine, that will give a good dense permanent black that will not rub off. The celluloid has a matt surface.—**CELLULOID.**

1. We cannot tell you what is the process referred to, but we imagine it is a carbon method. 2. Carbon, although a gelatine process, is certainly the most suitable for the purpose. We should advise you to apply to a maker of carbon tissues, or to one or other of the firms making a specialty of carbon printing.

**SULPHITE.**—1. Please say if enclosed sample of soda sulphite is all right for making up No. 2 pyro soda developer, as follows:—

Soda sulphite .....	2 oz.
Soda carbonate .....	2 oz.
Water .....	20 oz.

I ordered 4 lb., and this is the kind sent. 2. Is it as good as the "lump" thing? 3. Also please say if enclosed will keep as well as if in the larger lumps. 4. What is the proper term to use in ordering soda sulphite, etc., so as to get it in pieces about the size of peas?—**J. A. C.**

1, 2, and 3. These questions can only be answered by trying the sulphite. Simple inspection of the sample will give no information. The appearance of the sample is unusual, but its quality and keeping power can only be determined by using it for a considerable time. 4. The size of the crystals varies greatly with different makes. If you want good sulphite, ask for that made by some special manufacturer of repute.

**MOUNTING.**—In your issue of March 13 last you gave an account of "An Improved System of Mounting" (written by Mr. Nelson K. Cherrill in the "Photographic Monthly"). Could you give me the proportion of shellac and methylated spirits used to make the shellac varnish; also the proportion of acetone and alcohol to form the mixture to rub over the surface of the mount or paper to which the print is to be attached?—**W. G. WARD.**

You had better get the March issue of "The Photographic Monthly," in which the full article appears. Publishers, Dawbarn and Ward, 6, Farringdon Avenue, E.C.

**SELF-TONING.**—(1) As permanent. (2) Not much. (3) We certainly think so. Similar prints made on plain paper years ago have proved permanent.

**NERO and Others.**—In our next.

**N. S.**—Most probably the photograph is the copyright of the photographer, in which case you expose yourself to legal action by making a copy.

**E. A. THORNLEY.**—Marion and Co. 6s. 6d. a pair.

**VARIOUS.**—1. The "Journal" for 1905 gives on page 712 a list of comparative plate speeds: H. and D. 200 = Watkins 133; "Journal," 1908, page 945: H. and D. 200 = Watkin 294. This latter corresponds closely with the Wratten cards. I use a Watkin meter, and sometimes use plate for which only the H. and D. numbers are given. How can I know to which Watkin number this is equivalent? 2. Give quantity of acetone sulphite to each or of hypo for acid fixing bath. 3. Will proportion of acetone vary for different strength of fixing bath? I use 4 oz. of hypo to 20 oz. water for plates and 2 oz. hypo to 20 oz. for prints. 4. How long should prints or plates remain in these baths when using acetone sulphite?—**J. W. G.**

1. A more recent table in the "Almanac" for 1908 gives the rules for conversion as follows:—To convert H. and D. into Watkins, multiply the H. and D. number by 50 and divide by 34. Practically the Watkins No. is  $1\frac{1}{2}$  times H. and D. This has been worked out by Dr. Mees for Wratten plates, but would probably apply with fair accuracy to other plates. 2. The exact

quantity is not important—say, 50 grains. 3. The given in 3, that is,  $\frac{1}{2}$  the quantity of the hypo, may 4. A little longer than usual.

**TAX ON VEHICLE.**—I am located in a small country town will see by the heading of this letter, and a great port trade is outdoor photography, taking gentlemen's houses, weddings, and such like, groups, etc. Sometimes I have to do a dozen miles to execute an order. Two years ago I started a trap, a small wagonette, as I thought it would prove less than having to hire one or pay railway fare, with the idea that I could now and then take the wife and children for a drive. Now I find that the income tax people have taxed my vehicle. On my complaining to the collector he tells me I have no power to take it off, and that I must appeal to the Board of Inland Revenue. How am I to act, as I was told before purchasing the vehicle there was no duty on one that was used for business purposes?—**TAX.**

What you were told is quite correct, provided the vehicle is used wholly and solely for business purposes. But according to the statement, you employ yours for pleasure as well, then the duty is rightly imposed, and we do not at all think you are out of paying it, even if you think it advisable to appeal.

**AMATEUR.**—If the chloride of gold, when dissolved, became discoloured, it is obvious that the "distilled" water was not pure. The distilled water sold by druggists is often not so pure as it should be for photographic purposes. It is quite possible, that the water was not at fault. The solution may have been made in a bottle that was not chemically clean, in which case the result would be the same as if the water were impure. You probably know which of the two was the source of the trouble.

**THE CARBON PROCESS FOR PROFESSIONALS.**—Messrs. Illingworth and Co., in accordance with their announcement on another page, are drawing the special attention of the professional photographer to the carbon process, all the materials they have for several years manufactured, of excellent quality, may be pointed out that even those studios which do not possess their own carbon work can be well served by the firms working carbon, among other processes, for professional photographers by others who do carbon printing exclusively.

**MUNICIPAL PHOTOGRAPHER.**—Mr. G. Carpenter, photographer of the Wimbledon Town Council, has this week had his salary increased from £98 to £100 per annum.

**THE OIL PROCESS.**—Mr. Evershed will give a demonstration of this process, to which he has devoted quite special attention, at the meeting of the South London Photographic Society, on Monday, May 11th, at 8 p.m. The meeting, to which visitors are invited, is held at the South Art Gallery, Peckham Road, S.E. Admission tickets will be 2s. 6d. by Mr. H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

**THE "RAJAR" CAMERA,** offered monthly by Messrs. R. and J. Mobberley, Cheshire, for the best print on "Rajar" paper. It has been awarded to Mr. F. Bever, Watford, this print has been judged the best received during April. The paper on which the print was made was purchased from Messrs. The Postal Printing Company, Rotherham.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are required to be approved by the Publishers, and advertisements must be absolutely without condition, expressed or implied, as to what portion of the paper.

## SUMMARY.

Accompanying the present instalment of the articles by Mr. Drinkwater Butt we present with this issue a set of drawings of a complete photographic establishment on a town site.

To-day is the last day for entries for the exhibition of the Society of Colour Photographers.

An exhibition of Mr. Furley Lewis' portraiture is now open at the Royal Photographic Society and will be reviewed next week.

"What to do with our girls." An exhibition of crafts suggested suitable for feminine employment is now being held in London. (P. 374.)

The ozobrome-oil process and progress in time development appear our Anallecta column. (P. 382.)

A note on the fitness of detail in small and large pictures respectively will be found on page 374.

Two illustrated articles deal with the new studio of Mr. F. A. Ainslie, in Bond Street, and with Messrs. Griffin's new professional department. (P. 380.)

A description of some methods of flashlight practised by American professionals has been published. (P. 376.)

Mr. W. Michell contributes some practical notes on burnishing, bossing, and plate-marking. (P. 375.)

Some editorial notes on the practice of photography in hot countries appear on page 374.

Mr. W. T. Wilkinson, at the L. and P., describes a method of producing reversed negatives direct. (P. 385.)

Extensive use is being made in Germany of picture postcards for educational purposes. (P. 385.)

According to a Consular report, a brisk trade among amateurs and professionals is being done in Turkey. (P. 381.)

A method of ceramic photography and improvements in cinematographs are among the patents of the week.

## EX CATHEDRA.

### Radiography in Medicine.

A new application of radiography in the service of medicine and jurisprudence has just been mentioned in Paris. Some time back it was announced that in cases of suspended animation, where it was uncertain if death had taken place or not, all doubt could be resolved by radiography, a slight pulsation of the internal organs being registered on the sensitive plate. Now, following on researches on the radiography of the foetus, M. Vaillant states that the difficult problem of deciding whether a child is still-born or not can be settled in a similar fashion. If the radiograph shows only the elements of the skeleton, with no impression of the stomach and viscera, the child has not breathed. If, however, breathing has taken place, even for some minutes, the stomach gives a stomachic "trace," the more distinct the longer the period of respiration has been.

\* \* \*

### The Colour Exhibition.

At the time of writing, two days before the last day for exhibits to reach Wellington Street for the forthcoming exhibition of the Society of Colour Photographers, we would again draw attention to the final arrangements for the display of prints and transparencies in processes of colour photography. The means for illuminating Autochrome and other transparencies provided last September at the British Journal Offices were acknowledged to be the best provided at a public exhibition. They have been further improved for the forthcoming show, and though it is doubtful whether all the work sent in can be shown, there is no doubt that the space at disposal will be filled with a remarkably fine selection of Autochrome work. Repeating previous announcements, pictures and transparencies should be sent addressed to Mr. Henry J. Comley, 24, Wellington Street, Strand, W.C., to arrive some time during to-day, May 15.

\* \* \*

### Distortion with Lenses.

A writer in the "Photographic Monthly" gives some reproductions from test charts to illustrate the comparative effects of an anastigmat, R.R. lens, and a single achromatic lens. The results are very instructive, as they show clearly the defects of the R.R. lens as regards distortion, and prove the fallacy of the idea that its symmetrical construction gives results free from distortion. It has often been explained that the symmetrical construction only obviates distortion when the lens is used to copy on a scale of full size, and that distortion exists when the lens is used on distant objects. In the cases illustrated the lens must have been fairly near the object, yet cushion distortion is very obvious with the R.R., though the anastigmat shows no signs of it. Probably the

fact that the distortion given by the R.R. is of the cushion variety is the reason why it is so seldom noticed. The effects of this are not nearly so objectionable as those of the barrel variety given by single lenses, and probably the majority of photographers overlook them even when they are present to a fairly large extent. In other lenses the presence of distortion is often undetected owing to its peculiarly complex nature. It is a very common thing for the same lens to give both barrel and cushion distortion. The latter variety may exist at the margins of the field and the former at a part intermediate between the centre and the margins. At the part of the field where the one variety of distortion changes into the other, straight lines are represented as straight. These straight lines will probably occur near the margins of the plate in use if the lens is not being employed at a wide angle; or, in other words, they will exist just where the user of the lens is likely to be looking for signs of distortion, and as he is pretty certain to look for curved lines he will assume that his lens is distortion free. The lines, though straight, may be wrongly situated, but this fact will not be apparent, and in all probability the worker will not know that straight lines may exist with a distorting lens.

### What To Do With Our Girls.

There is now open at the Prince's Skating Rink, Knightsbridge, an exhibition of the arts and crafts in which, so it is suggested by the promoters, opportunities are afforded for girls of intelligence to earn their own livings, or, at the worst, to cover expenses in pleasantly occupying their leisure hours. The propositions thus offered to the feminine choice range from making artificial flowers to breeding donkeys, to say nothing of motor tuition, leather and metal work, miniature painting, and, of course, photography. We could not help being impressed by the ardent enthusiasm of the ladies in their occupations—did they not admit to us being "awfully keen" on them?—and no less by their evident blindness to the defects of much of their handiwork. The almost universal willingness to take pupils in their crafts suggests the rather discomfiting fact that these *petits métiers* themselves are not all that can be desired in a remunerative sense. But of industry pitifully wearing itself to the bone in some cases, a visit to the exhibition will show a score or two examples. Our halt at one photographic stall brought before us some effort mis-expended on the hand-drawing of crayon enlargements from small photographs; at another table we were offered, on behalf of a West End photographer, a 5s. coupon entitling us to a photograph usually not obtainable under a guinea. We came away wondering whether the would-be girl-photographers had divined the significance of this latter fact to themselves.

### Detail in Photographs.

Mr. G. A. Storey, A.R.A., in his lecture on "Art and Photography," given at the R.P.S. a few weeks ago, dealt with the matter of detail in a manner that may seem strange at first to many photographers. The position he took up was this: Detail in small images tends to give an appearance of littleness, while in large pictures it simply looks natural. The reason of the dwarfing effect of detail in small images is fairly easy to understand. In general, small scale suggests distance, but fine detail denotes nearness, and when the two co-exist we can only reconcile one with the other by assuming small size. From this we may argue that in the case of large images, say nearly full size portraits, the size suggests nearness, and detail is then expected. If it is entirely absent the effect is difficult to account for. If we assume the lack of detail to be due to distance, then the big scale denotes gigantic size, while if this seems unreasonable we are apt to feel that

something has gone wrong with our eyesight. It is very curious that so many photographers seem to look upon detail from quite opposite points of view to those we have mentioned. They tolerate intricate detail in small images, probably because it looks pretty, but aim at most obvious fuzziness in large pictures where detail is most in place. Possibly this is due to want of consideration of the various factors that tend to suggest distance or the reverse. One of these factors is, of course, depth, and this, naturally, should vary in quite the opposite way to the detail. For example, if our attention is directed to a very near subject we see all the detail in that subject, while more distant objects are practically ignored, and are therefore best represented without detail. If, however, the principal object is moderately distant, we see very little of its detail, while its general definition is very little better than that of much more distant objects in the background. In this latter case fair depth, but little detail, is desirable, while in the other detail is wanted but practically no depth.

### PHOTOGRAPHY IN THE TROPICS.

A RECENT article by Mr. E. W. Foxlee on the working of the carbon process in tropical countries having brought us several requests for a few hints on the precautions advisable in the case of other branches of photography, we will endeavour to give a few general precautions of a kind which may be profitably applied both by those contemplating residence in hot, humid countries, and by others who may intend only to journey through them. Both must realise that photography as a profession or a pastime is hedged about with difficulties when practised in a country where the thermometer may range from 90 deg. to 120 deg. Fahr., and that in the hot and dry season it can be carried on at all only at considerable inconvenience, whilst in the wet season the conditions are worse still. A moisture-laden atmosphere at a temperature of 90 deg., such as is common during part of the year in India, the West Coast of Africa, and other countries, obviously puts the photographer at considerable disadvantages, since not only all materials become more or less adversely affected, but apparatus as well. It is only the very best of the latter which will not succumb in a year or two, and become useless; and with even the very best every care must be bestowed upon it when in use, and when stored away, for the moisture and destructive insects will find access through almost everything. In the wet season the glue will soften and possibly ooze out from the dovetailed joints of apparatus and the panels of the dark slides, so that they become loosened. Some time ago in conversation with one of our oldest, and best, camera makers, we asked if there was any actual advantage in brass-binding cameras when they were made of well seasoned wood, and were of the highest class workmanship. His reply was to the effect that there was practically none if the camera was used with ordinary care in this country. But if it was for India, or such places, there was a decided advantage in the brass binding, since, in the hot, wet seasons, the glue in the joints became softened, and the joints thereby loosened. The brass binding, however, held them firmly in position until the glue was again dry and hard, so that the apparatus in the end suffered no very material injury. Our informant added that the whole of the cameras he had made for India—and he had supplied many—were all substantially brassbound, and that such a course invariably proved the most economical in the end.

The bellows of cameras usually suffer badly in tropical countries, particularly during the wet seasons. The

her absorbs moisture and becomes mildewed, while foundation also softens by absorption of moisture. It loses its rigidity, and the gussets no longer keep their shape. Another great trouble in such countries is the attacks of insects, which sometimes eat the leather of bellows, and the glue in its foundation, and sometimes the holes in the woodwork to a troublesome degree. What has been said it will be seen that it is only the best cameras that will prove of service for any length of time in tropical climates. We would caution all who are going to such places, even on a tour, to avoid dealing with them any of the cheap, "slop-made" apparatus, which there is now so much on the market, as they will mainly regret the course when perhaps too late to reverse the outfit with another. It must not be assumed we condemn all low-price apparatus, for, as a rule, it gives excellent service when used in this and similar countries. But in tropical climates most of it would lead to disaster in greater or less degree.

In the foregoing we have been dealing with cameras and especially, but lenses should not be dismissed as requiring no attention. In tropical countries they should receive the greatest possible care and protection, or they will suffer materially from atmospheric conditions. Some time ago while we were shown a large portrait lens, by one of our best makers, that had been in use for some years in India. It was in a sorry plight. The lacquer had perished and the brasswork become corroded to a great extent. The glasses also had suffered badly, as the surface had lost their polish through erosion. The instrument in the first instance cost something like £60, but in the condition in which we saw it did not look worth as much as 7 shillings. However, after the brasswork had been repolished and the lenses re-polished by the maker, it was again a servicable instrument. We merely allude to this matter to point out that lenses require the greatest care in tropical countries, or they may suffer unsuspected deterioration.

Turning from apparatus to materials, difficulties have to be met. Plates, films, and papers should always be kept in specially packed in zinc-lined cases, soldered down, and labelled that they must be stored in a cool place and not near the vessel; if placed near the boilers the continued heat on the long journey would cause deterioration. Some

brands of plates are credited, and rightly so, with possessing greater keeping qualities under trying climatic conditions than others. It may, however, be taken as an accepted fact that plates of moderate rapidity, other things being equal, have better keeping qualities than those of ultra rapidity. In our climate there is little trouble with frilling in the case of plates at present made, but where tropical heat prevails it will be almost always necessary in working to keep everything as cool as possible, and to make free use of formaline or other hardening agents. It will also be an extra safeguard against frilling to rub the edges of the plates round with a piece of paraffin or beeswax before commencing the development. It involves but little trouble, yet the latter may often be expended to advantage.

With regard to printing processes it may be truly said that the easiest of them to work under tropical conditions is the old albumen paper, where the paper is sensitised by the worker as required for use. Gelatine P.O.P.s, as most are aware, sometimes give trouble, even in this country, in very hot weather. That, however, has been greatly minimised by the makers of most brands during the past year or so. Yet P.O.P.s, by reason of the free nitrate of silver in them, have not the same keeping properties as have development papers. The latter have a much longer life under severely adverse conditions, and there is no reason why, with the many methods of toning now in vogue, they should not be employed in the tropics in place of P.O.P. Results that can only be distinguished by experts from those made on P.O.P. can be produced upon many of them, and there is less trouble in making them in exceedingly hot weather. We are now alluding more particularly to the slow contact and gaslight papers, which have excellent keeping qualities.

One final note on a minor, but not unimportant, point. Photographic dealers in tropical countries know by experience the goods best suited to their climate, and they take care to import—which, by the way, they do chiefly from this country—only such as they know will prove satisfactory to their customers. Therefore a tourist, if he happens to run out of the supply of material he took with him, will do well to replenish his stock with what the dealer recommends, even though it may not be his favourite brand.

## BURNISHING, EMBOSSING, AND PLATE-MARKING.

In burnishing prints with a bar burnisher it is imperative that the bar be perfectly true and free from scratches, as any which come to lie across it would certainly produce fine lines on the print; longitudinal scratches are of somewhat less importance. And there, however, be some crosswise scratches, they may be removed by rubbing the bar on an oilstone, working it always longitudinally, and keeping it perfectly flat from end to end, so that the ends will be ground away to a greater extent than the middle, and an even polish will not be obtained all over the bar. In working the bar on the oilstone care should be taken to give it a slightly rounded and not a quite flat face. Holding the burnishing bar, it should be equally heated, and not more so at one end than the other. Carelessness in this respect will give rise to an unequal gloss on the two sides of the print. With regard to the temperature of the burnishing bar, it should be about as hot as a laundry-iron is made—namely, that is, as hot, or a little hotter, than the hand can bear. Before the prints are burnished they require to be heated to prevent them from sticking to the heated bar. The lubricant for the purpose is Castile soap. 45 grains, dissolved in 1 pint of methylated spirit. It is merely rubbed thinly over the surface with a pledget of soft rag or cotton-wool.

### Enamellers.

Of late years bar burnishers have been greatly superseded by enamellers. These are really rolling presses, with small rollers heated by gas or spirit. The prints are simply passed between the rollers, which, being small, impart a very high surface. The rollers of enamellers are nickel-plated to avoid rusting, and care must be taken that they do not get scratched or otherwise damaged, as the injury would show on the unfinished prints. Sometimes—though not often—the nickel-plating may become loosened or separated from the iron. When that happens the rollers must be sent to the makers of the machine to be replated. The advantage of enamellers over bar burnishers is that the larger size pictures can be better dealt with, and the prints are not so curled in the operation.

### Die Presses for Cameo Photographs.

At the present time there is not the demand for pictures with the raised, or cameo, surface there was some few years ago. For producing these, embossing presses are supplied. These are screw-presses, with thick brass dies with an oval or other shape opening; between the die and the top of the press is a thick pad of indiarubber. The print being placed between this and

the die, the screw is tightened so that by the elasticity of the rubber the centre of the picture is forced up, while the other portions remain flat. The pressure should be left on for a minute or so, the embossing thus keeping its form permanently. The embossing presses as sold are of small sizes—cabinet or smaller—but by having dies of large size and rubber pads to correspond, ordinary screw letter-copying presses may be utilised. For these larger sizes hard wood dies may be made to suffice, though, of course, metal ones are preferable. Some years ago I saw some 10 x 8 portraits that had been embossed in this way, and they were very attractive. The thickness of the die, and that of the pad, determines the degree of convexity. If, in place of a thick die, a thinner one and thinner pads be used, a lunette relief instead of a quite convex one will be obtained, and this for the larger sizes is, to my idea, preferable. There is a simple extemporary way of embossing small pictures, say three inches and downward. All that is necessary is a zinc plate, say the eighth of an inch thick, with an opening of the desired size, a piece of plate-glass, and the stopper of a bottle that is round at the top. The zinc is placed on the glass, the print placed in position on it, and held firmly while the back is rubbed over with the stopper used as a burnisher. In this simple way very good small cameos can be made. Prints that are to be embossed are best mounted on thin cards, then embossed, and afterwards attached to a thicker mount by the edges only. If they have been enamelled the high gloss will not be disturbed. If the prints are of large size, and the embossing in high relief, it is well to put a pad of cotton-wool between the embossed portion and the actual mount, as then the relief is not so likely to be injured by pressure.

#### Plate-marking Mounts.

Plate-marking is not often done by the photographer himself. He usually purchases the commercial plate-sunk mounts now on the market. If prints on these mounts are rolled, much of the plate mark is destroyed, and if not rolled the print has not the same finished appearance it would have possessed had it been. Yet, rolling and plate-marking at the same time can be easily done by any one who is in possession of an ordinary rolling-press. A photographic rolling-press is practically a copper-plate press on a small scale, and it can be used in a similar way. There is required in addition two or three thicknesses of printer's blanketing and the plates, which latter the photographer can prepare for himself. At the dealers in printers' materials, copper, steel, and zinc plates of certain sizes are kept in stock, whilst others can be supplied to order. They are polished ready for the engraver. The steel are made more expensive than the copper, and they

are liable to rust unless kept with considerable care. However, copper ones are practically as good for our present purpose as the more costly steel. It will be well to bevel, neatly, the edge for the eighth of an inch all round. This can be done by the aid of a file. After the bevel has been filed down, the roughness left by the file must be taken out by working along the bevel with a piece of snakestone wetted with water, working it always longitudinally, and finally polishing with charcoal and oil. The finest emery paper—that sold by dealers in engravers' requisites under the name of "blue back." For different sizes and shapes, different plates are, of course, required; but, as just shown, they are easily made.

The plate-marking is done as follows:—A piece of paper, the size of the mount, is laid on the bed of the press; on this is placed the plate, face upward. The mounted picture—face downward, of course—is laid in position, the piece of paper on the bed of the press serving as a guide for register. On the two or three thicknesses of the blanketing are laid, and the whole passed slowly through the press. Owing to the elasticity of the blanketing much greater pressure is exerted on the picture and plate than on the margins, hence the plate-mark. In this way we have the print rolled and plate-marked at the same time. Prints so treated have a much neater and more refined appearance than those that are simply mounted on plate-sunk mounts and not rolled at all.

#### Zinc for Plate-marks.

In place of copper, zinc plates, which are much cheaper and easier to manipulate with the file, may be used, but they are not to be recommended on account of their being easily scratched or damaged. It is well, as just said, to have the plates bevelled at the edges, as it gives a better finish to the pictures, though they may be used if merely rounded. It goes without saying that the more highly polished the plates the higher the gloss on the surface of the prints. Should a plate become accidentally scratched, the defect will show in the finished picture if the plate is used in that state. However, the scratch can be got rid of by working it out with a stick of charcoal and oil. A special charcoal for the purpose is sold by all printers' and engravers' sundrymen. After the scratches have been worked out the surface is finished off with a small piece of the blue back. In polishing the plate with charcoal, or with the emery paper, it must always be worked in one direction only, otherwise a perfect polish will not be obtained. A certain kind of plate-marking may also be produced by employing a piece of hard cardboord or a hard mount in place of a metal plate, but the effect obtained is not nearly equal to that secured when the picture is rolled in contact with metal.

WM. MICHELL.

## THE FLASHLIGHT IN PROFESSIONAL PORTRAITURE.

[Of late in this country the magnesium flashlight as a method for regular professional portraiture appears to have largely lost what little vogue it once possessed, a natural consequence, if the arc lighting, which has slowly but surely come to the front. Nevertheless, flashlight may be of service, particularly to the professional who cannot obtain electric supply, and we therefore quote some portions of an article in the current issue of "Camera Craft," by Charles R. Ogilvie, who strengthens a strong argument for flashlight by reproductions of some excellent portraiture done by it.—Eds. "B.J."]

BUT to return to our advantages; there is next the power to catch the most fleeting expression, owing to the short duration of the flash. The time involved is less than one-twentieth of a second, and, with a good powder, even shorter. The experienced photographer will recognise the value of this, particularly in the case of children. To be sure of the desired expression, and that there will never be a failure, because of a move, are of inestimable value, and should commend it to all, for occasional,

if not for regular, use. One has absolute control over the amount of exposure given. If a certain number of grains of powder are found to be right, one has but to measure out the desired amount each time, and the negatives will develop automatically and be of exactly the same quality throughout a number of sittings. The necessary amount of retouching is greatly reduced. The difference between flesh texture and drapery is always rendered correctly. Both of these advantages

due to the somewhat orthochromatic quality conferred by the material. The rendition of drapery, either light or dark, is perfect, the quality of the hands against either calls for no attention from the photographer; that is all taken care of by the yet searching light.

The cost of each exposure is a fractional part of a cent. A serviceable apparatus costs less to install and maintain than an ordinary set of studio blinds. Any room that is large enough for the lens employed, can be used, and the portability of the apparatus prevents much of the necessity of shifting the camera about for varying effects. In addition, there is no trouble with leaky skylights and broken glass, no expensive electrical repairs or unexpected breaking down of delicate mechanism.

to the apparatus used, its forms are as varied as are the lights employed by different photographers; in fact, the variety is even greater. The most effective arrangement is, perhaps, that employed by Mr. Morgan. He has built a partition of tracing cloth extending from floor to ceiling, and at two feet from the front wall of his room. The flash lamp is placed in that narrow enclosure, and the smoke flows out of an ordinary window lowered at the top, a window, of course, cut in the wall behind the tracing cloth partition. A door at the end makes the placing of a new charge in position but work of an instant. The light is used exactly the same as a light, except that the raising or lowering of the standard for moving the powder pan, together with the moving of the frame from side to side, does away with the necessity of using screws or adjusting them for various effects. The cut herewith shows a piece of apparatus used by a photographer in the Middle West. The swinging frame, six feet

square, is backed with asbestos-covered canvas, and the front is covered with semi-transparent cloth. It is open at the bottom, but closed at the top, except for the flexible canvas pipe which connects with a chimney, window, or other opening to the outer air. The smoke is driven out by means of a small electric fan located in the end of the pipe, and operated by a single battery cell. The flash lamp is supported on a frame just inside the small door shown open at the side. Exposure is made by pressing a bulb, which explodes the powder and opens the shutter at the same time.

A third worker uses a light wooden box about three feet square, lined with asbestos paper, one side, the front, left open except for a covering of thin muslin. This is provided with a smoke outlet in the form of a flexible chimney and with a door for placing the powder on the pan within. This box is swung from the ceiling, and can be moved about and inclined at any angle by means of a couple of cords. The powder is ignited by means of a push button, which causes a weak current to pass through a short length of very fine wire on which the powder is placed. This short wire becomes red hot the instant the button is pressed and explodes the powder.

I have not given any diagrams showing position of lamp, sitter, and camera, for the reason that this is intended mainly for the professional, and the light illuminated surface is used exactly as one would employ a like uncurtained portion of the ordinary skylight. I have, however, neglected one feature, and that is a means of focussing and also of studying the lighting before the exposure is made. This is easily secured by having an incandescent light, or even a group of two or three, suspended by a cord in such a way that it can be hung directly in front of the intended flash. In the box-shaped apparatus I have described, two of these lights are a permanent fixture near the centre of the bottom of the cloth-covered side, through which the flashlight reaches the sitter. A pliable connection of suitable length joins these to a near-by lamp socket. If such light as may be used is found hardly sufficient for critical focussing, the difficulty may be overcome by cementing, with a drop of Canada balsam, a microscopic cover glass to the inner side of the focussing screen. The balsam fills up the rough surface of the glass, giving a clear glass spot through which one may secure an aerial image by means of an ordinary focussing glass.

It should be borne in mind that a concussion follows the explosion of all flash compounds, and if one uses a powder that requires more than a few grains to secure the desired amount of actinic light, it will be necessary to have an opening in the box or bag used, to allow of the expulsion of air attending the concussion. This can take the form of a flap that will swing outward and fall back into position before the smoke can escape. Another thing I would like to point out, and that is, the advisability of removing the cloth through which the light passes and washing it out from time to time. Tracing cloth, having a smooth surface, catches little in the way of dust from the repeated flashes, but other cloth is liable to become clogged up and prevent the light from passing through as it should. If the cloth be soaked for an hour in a gallon of warm water in which has been dissolved seven ounces of ammonium phosphate and two and a half ounces of common soap, and then hung up to dry, it will be rendered practically fireproof.

CHAS. R. OGILVIE.

**P.S. AFFILIATION.**—A meeting of secretaries of affiliated societies in London and district was held at 66, Russell Square, on Monday evening, May 4, presided over by Mr. P. Bale Rider, Chairman of the Executive Committee. The meeting was the revival of a practice of considerable service some years ago, but which had dropped out of use recently. Between twenty and thirty societies were represented, and many matters of interest were discussed. It was decided to hold these meetings quarterly, and to make them of

service to secretaries in arranging their programmes. The subject of interchanging lectures was fully discussed, and it was arranged to send out each month to secretaries a list of lecturers who were willing to assist affiliated societies, with the subjects of their lectures, fees, etc. It is hoped that affiliated societies in the provinces will follow London's example and hold meetings of this kind in their various districts, as such combined gatherings may be made of much benefit and interest.

## THE MODERN NOTE IN THE DESIGN AND FITTING OF PHOTOGRAPHIC PREMISES.

### VII.

[In drawing to a conclusion the articles on the principles which should guide a photographer in the design and decoration of his place of business, we come to the consideration of a complete photographic establishment, consisting, in fact, of premises such as few living photographers would feel justified in putting up. Yet the scheme of such a building in its various parts may be commended to the study of even the small photographer on account of its giving details of arrangements which can be abstracted in pieces from their surroundings and utilised in a far less elaborate setting. Therefore, we present this week a set of drawings, made for readers of the "British Journal" by Mr. Drinkwater Butt, part of whose description of them appears this week, whilst the remainder concluding the present series of articles, will appear next week.—Eds. "B.J."]

In the early days of photography, and when competition in business had not reached its present stage of acuteness, almost any kind of a glass house appears to have done duty for a studio, and any sort of premises to have been deemed suitable for the conduct of the operations of professional practice. To-day, however, when, as in all business enterprises, there is in photography not only more capital invested, but also much more system and organisation needed to work such a concern profitably, by the production of first-class results at moderate prices, all possible conveniences of housing, as well as all kinds of labour-saving appliances, have to be resorted to, and much more attention is therefore paid to the location, construction, and fitting up of such establishments. Wherefore, a few words on the planning of photographic premises may not be out of place.

To illustrate the general principles which should guide the designer who has to consider such a matter, I have prepared the accompanying set of plans; choosing a town site, with its attendant conditions and difficulties, as being the most general form in which such a problem is likely to present itself. We have, as will be seen from the drawings, a plot of land having a frontage of 25 ft. to the street, and a depth of 100 ft. from front to back. We have supposed, also, that its greatest length runs from east to west, as that is a point one would naturally look for in choosing such a site, in order to have the best opportunity of obtaining the greatest amount of north light for an evenly illuminated but not directly sunlit studio. We have further presupposed the very probable difficulties that both sides of the site, for at least 50 ft. back from the frontage, are occupied by existing buildings of not less than 40 ft. in height; that we are also similarly prevented from getting any lighting at all from any part of the south and east sides; and that there are no means of access save from the street frontage only. The problem, then, is to construct a building that shall give us the greatest amount of accommodation, suitable for the conduct of a large general photographic business, within and under these limitations and difficulties.

#### Division of the Working Premises.

The first point considered has been the desirability of separating what may be called the public from the working part of the premises; while yet allowing easy and quick access from one to the other at convenient points. This has been done by concentrating the former upon the front portion and the latter upon the back part of the site, an arrangement that also keeps all the necessarily large and high apartments together in one block, and the lower and smaller ones in another, with a consequent facility of planning and economy of construction. Each group occupies, approximately, about one-half of the site, the rear portion including the open space necessary for light and air at the back of the building. Entrance for goods and assistants to the working part of the premises, without passing through the public rooms, is provided by the passage shown on the ground plan, which receives its light from the fanlight over its door in the front elevation, through a half-glass door into the covered way at the further end, and by the glazed door and partition shown at the foot of the main staircase in the Section A.B. Clients and the public enter by the other door in elevation, through the lobby into the reception room, whence they are easily sent by stairs or lift to the exhibition gallery, principal's office, dressing rooms, or studios, as required.

#### The Daylight Studio.

The last-mentioned apartments are, of course, the most important in the building, and their planning naturally received the next atten-

tion. The only suitable place for the daylight studio, on such a site, is obviously the top floor, where it alone can receive its light from the north, at some 40 ft. from the ground, unimpeded by the adjoining structures. On a more open site one would have kept the studio on the ground floor to avoid the trouble of sitters ascending to it, but in the present case one can only minimise that difficulty by the provision of a lift, in the well of the staircase, going up through all floors of the building. With its light on the north side, the length of the studio must naturally run east and west, and we then find that when we have taken space enough for a sufficiently dignified staircase running round a square lift well, we can get a longitudinal internal dimension of 31 ft. as shown, which, however, does not include the further 4 ft. given by the depth of the semi-circular recess at the east end into which the camera could on occasion be run when greater length was required. The principal purpose, however, of this recess is for it to form, by means of its plastered and flat-tinted, curved wall, a naturally graduated background, which, under ordinary conditions of lighting, would give a dark behind the lighted side of the sitter, and light behind the shadow side, and do so in a manner much more suggestive of space and atmosphere than any ordinary painted background. It would be ceiled with two light canvas-covered frames, hinged at the middle, as shown by dotted line on plan, either of which could be raised by cords and pulleys worked from the lobby of dark-room, so as to alter the effect and gradation of the background by the admission of light from the special skylight shown on the roof plan immediately over the recess, and so give an infinite variety of artistic effects with great ease and simplicity.

#### Some Novel Studio Features.

The sectional form of studio chosen, as will be seen by reference to the Section E.F., is that known as the "single slant," in which the glazed portion is all in one plane, and consequently unbroken by the wall plate, which, in ordinary studios glazed at side and roof, often causes double high lights in the eyes of sitters. It has all the advantage of allowing of the more ready construction of a roof which is really weather-proof, which throws off snow at once from the glazing, and which admits of the more easy execution of repairs. The roof, as shown, is carried on two steel principals, the position of the tie rods of which is indicated on the plan, their height above the floor, as shown by the section E.F., being 9 ft., so that there is plenty of room for the movement of background stands, etc., beneath them. It may also be noted that the steep pitch of the "single slant" is sufficient to prevent the sun, even at its highest midsummer altitude of 62 deg., from looking over the roof into the studio, so that trouble from its direct rays would never be experienced. The glazing of this north light, which would be executed on the well-known "Simplex" principle, goes, of course, to the whole height of the studio, some 14 ft., and with a length of 22 ft., and an outward slope of 6 ft., affords an ample lighting area for the largest groups which the studio could accommodate, either end of the apartment. For ordinary work, of course, most of it would be obscured by blinds, of which there would be a double set, on spring rollers, one working upwards from the bottom, and the other downwards from the top. The window at the west end of studio would, of course, also be kept curtained, except when it might be required to equalise the lighting on large groups or objects, or when it was itself used as an accessory or background, or for obtaining special lighting effects, to facilitate which purposes its leaded lights would be glazed with white rolled cathedral or ground glass. Another fixed decorative feature which

might be used as a background and accessory is the "practicable" window opening on to the landing at the east end of studio, outside which might at any time be placed an outdoor painted background, which would be well lighted from the two skylights which, as shown on the roof plan, illuminate the main staircase; and others are also the doors, the mantel with its adjoining seats, and even the walls, which would be appropriately and usefully covered with "Lincrusta," or other similar relief decoration, plainly coloured to harmonise with the general colour scheme of the whole, which latter should be of soft, warm greys, slightly relieved with pale reds and yellows, so as to produce an artistic and pleasing effect without detracting from the general actinism of the light reflected from the walls. The pale cream or ivory tinted ceiling might be left plain or covered with a low relief decorative material as preferred. The floor would be of oak parquet, and, to facilitate the easy movement of background and camera stands, would be left uncovered, save for a few suitable mats or rugs in places.

For ventilation there would be a couple of small Boyle ventilators in the roof; and for heating, a couple of radiators, supplied, as in the whole of the rest of the establishment, with hot water from the heating apparatus in the basement. The fireplaces shown in the two studios and exhibition gallery are mainly for the sake of appearance, and although their open dog-grates would be used as required, the principal source of heating would be the general hot-water system. The radiators belonging to this, for the sake of avoiding confusion, have not been shown on the plans, but, of course, they would be fixed in every apartment. In the daylight studio they would be placed at each end of the north wall, and under them would be the ventilating inlets by which the outside air would be both filtered and warmed on its entrance, the former being especially necessary in smoky and foggy towns to preserve a clear atmosphere in the studio under all weather conditions. For ensuring coolness in a hot summer, water-pipes pierced with small holes at intervals of a few inches might be run along each side of the zinc flat, so that a gentle flow of water might, when desired, be made to run down either the slate of glass side of the roof, on the latter part of which it would also be very useful for cleaning purposes.

#### Dark-rooms and Dressing-rooms.

The dark-room is, of course, made to adjoin the studio, but is separated from it by a small lobby, in order that by the shutting of a door before the other is opened ingress and egress may be at times obtained without the admission of actinic light, an important point when an assistant may be developing or filling slides while operating is going on in the studio itself. The fixed fittings would include lead-lined sinks, with hot and cold water supply to each, shelving, and benches with cupboards under as shown on plan and Section A.B. Over the sinks are windows, well screened in the building at the back from the direct rays of the sun, and each of these would be fitted with sliding glazed shutters, so that day, yellow, or white light could be obtained at will during the day, while at night the room would be illuminated by electric lights similarly screened, for the same purpose. Special ventilating ducts for this room and the one below it are shown on the plans, plenty of fresh air being a necessity in dark-rooms if good work is to be done and health maintained.

Descending a few steps from the daylight studio landing, we have the passage leading to the dressing-rooms, which are thus conveniently situated equi-distantly from the two studios. They are two in number, one for ladies and one for gentlemen, and have each two windows, beneath one of which would be placed the dressing-table, and beneath the other, as shown, a lavatory-stand fitted with hot and cold water supply. Each room should also have ample accommodation for the outdoor and other garments of sitters. For sanitary convenience, lighted and ventilated from the roof, will be found in proximity.

#### Electric Light Studio.

Again descending to the second floor, we have next the electric light studio, situated immediately beneath, and of the same size as, the daylight one above. This is intended for use at night, or on dark or foggy days, with a movable arc or incandescent electric light, or one of the good patterns now on the market, or with any of the similar gas or magnesium appliances, as preferred by the operator. It would also be very useful for copying, the photography of objects, sketches of art, etc., with which it is not desirable to occupy the

other studio during the busy season of portrait work. It is shown, on the Sections A. B. and E.F., as decorated with panelling to the height of 8 ft., over which is a plain or decorated frieze to the cornice. This panelling might be executed in oak, or at less expense in soft wood and painted, and in either case would form, together with the doors, windows, and carved mantel, at many points a very useful and artistic background. As in the other studio, there would be a parquet floor, and a "practicable" window to the landing. The large western window, going the whole width of the studio, would, of course, be kept generally curtained, but portions of it might at times be used to obtain special lightings, and the whole occasionally to obtain a flood of direct daylight for copying and other purposes. Adjoining is a dark-room, similarly fitted to that above, but having, in addition, a convenient cupboard in its lobby.

#### An Exhibition Gallery.

Again below, on the first floor, we come to the exhibition gallery, an apartment at all times useful for the display of large specimens supplementary to those shown in the reception room, and, on many occasions, very valuable for organising special shows of the work of the proprietor, or of such collections of general artistic work as he might find interesting to his clients. Here, too, may be exhibited, on stands and tables, the series of photographs of local views, antiquities, and objects of interest, of which every large general photographic business ought to make a feature, printed in all styles, from the popular postcard to the framed enlargement. This gallery would be sufficiently lighted, by day, by the large window occupying the whole of the western end, and by borrowed light received through the principal's office, and the wide opening on to the main staircase. At night, incandescent electric light would be used, with a series of reflector fittings to throw the illumination on to the walls while shielding it from the eyes of the spectators. The apartment would be appropriately decorated in soft, warm browns, the walls being covered with brown paper or canvas above a rather more strongly tinted dado, to form a harmonious background for the monochromatic photographic work to be placed on it—the woodwork stained and polished—with draperies and curtains of a warm green relieved with citron yellow. A cream or ivory tinted ceiling, and a parquet floor, would complete the general effect.

Very conveniently adjoining this gallery is the principal's office, in a position which is practically central to the whole building, any portion of which can be easily and quickly reached from it. Its window also commands the whole of the back premises.

Again descending the main staircase, and noting in passing the obtaining of additional light for its lower portion by means of a circular window opening from the covered way on to its first half landing, we come to the reception room on the ground floor, with a lobby entrance from the street having an outer door to always stand invitingly open, even when in cold weather the inner glass one had to be shut. The show-window has been kept moderate in size, not only to obtain a better architectural effect in the elevation than can ever be got when huge sheets of plate glass are introduced, but also because the display of a small quantity of good work, well arranged, is always much more artistic and pleasing than a large and "fortuitous concourse" of what are often truly "incongruous atoms." The window space could be enclosed by a dust-proof glazed partition, which latter should not be obscured by any draperies which may be used, to the extent of excluding very much light from the reception room itself, though that apartment will also receive some light through the general office, and from the main staircase on to which it opens. Being, however, less well-lighted than the exhibition gallery above, its decoration should be kept proportionately lighter, and the woodwork and fittings might be of ivory-white or cream colour, with walls of a soft green and a dado of a darker tint.

The staircase might be of oak, with dull red walls, on which might be appropriately displayed the larger specimens of coloured work, such as life-size oil paintings, which would be out of place among the smaller and more generally monochromatic work shown among the more delicate and quietly decorative tints of the exhibition gallery and reception room.

The general office occupies a suitable position adjoining the latter, conveniently situated for easy communication with the receptionists, for the payment of wages, and the reception of commercial travellers.

DRINKWATER BUTT, F.R.P.S.

(To be continued.)

## A NEWCOMER IN BOND STREET.

BOND STREET and Baker Street, as everybody knows, represent the two colonies in London of the "fashionable" photographers, and Bond Street, by its intersection of the eastern part of Mayfair, is undoubtedly the more fashionable of the two. Hence no little interest attaches to the addition of a newcomer to the ranks of Bond Street photographers, and when we heard that Mr. F. A. Swaine had established himself at 106, New Bond Street we took an early

A Corner of Mr. Swaine's Studio.

opportunity of paying him a call. We knew him as a photographer of distinction in Southsea, where his work had drawn to his studio society people residing near this part of the South Coast, and we were naturally anxious to see the premises of this latest of West-End photographers. From the marble portico of 106, New Bond Street, the elevator silently raised us to the very threshold of Mr. Swaine's reception room, which we found furnished with some choice specimens of eighteenth century chairs and tables. Mr. Swaine has a

The Reception Room.

hatred of the artificial, and has banished from both his reception room and studio the sham furniture which is supposed by many photographers to be an indispensable part of their outfit. Mr. Swaine, however, has in his composition enough of the amateur—using that word in its true sense—to influence his practice as a portrait photographer. His first training as a photographer was gained with the late Walter Noah Malby, of Chichester, an exhibitor in the old days at the Royal Photographic Society's Exhibition. At

this time he was also a student of portrait painting of Mr. Fred Stratton at Amberley. Although the past sixteen years of his life have been about equally divided between the studios of Lafayette in London and Dublin and his own at Southsea, Mr. Swaine has shown enough of his portrait and landscape photography at the exhibitions to bring him about a dozen medals, and enjoys the distinction of having had a photograph of his purchased by King Edward.

His new studio in Bond Street strikes one at once as cheerful and cosy, an effect due evidently to the home-like furnishing and the invisibility of the gaunt and formidable-looking implements often to be seen in a studio. As our illustration shows, one end of the studio is furnished as a cosy corner and includes a real window, which, like other parts of the apartment, is skilfully used as a background for sitters. The great length of the studio—45 feet—further favours the photographer in thus indulging his fondness for portraiture with the look of a home-portrait about it, but with a photographic quality which the facilities of a studio enable him to secure. Mr. Swaine, of course, is provided with artificial illumination for use on the infrequent occasions when the natural daylight fails him and for the practice of the now important class of photograph the portraiture of ladies on their way to and from a levee or other society function. Mr. Swaine works almost exclusively carbon and platinotype, of which permanent processes he makes very varied use. His portraiture cannot be easily summed up, but in calling it out of the common we do not wish to imply that it is at all *outré* or eccentric. The aim of the photographer is evident at just that quality of naturalness which is often secured at the sacrifice of everything else in the amateur's chance snapshot. Mr. Swaine's case it is combined with photographic work of the best

## MESSRS. GRIFFIN'S "PROFESSIONAL" DEPARTMENT.

MESSRS. JOHN J. GRIFFIN AND SONS, LTD., is the latest firm to set apart a special department for the professional photographer. Their great block standing close to Kingsway, they have, within the past few days, completed arrangements whereby the professional worker can quickly and conveniently inspect or be shown the article which he desires for his use. Messrs. Griffin's professional li-

issued about three months ago, describes the many items of apparatus and materials which are intended solely for the portrait photographer, but the present move has been made in the belief that photographers within the area of Greater London will always prefer to inspect stock before purchasing new apparatus, while even those in the country will set aside part of a visit to London for the purpose. Hence the present department, which is under the immediate care of Mr. Tom Young, whose familiarity with the requirements of a studio are known to many photographers in London and the provinces. A great feature of the department is the offer for electric light portraiture. Messrs. Griffin are the special agents for the "Jupiter" flash arc, but they nevertheless show systems of lighting, such as the "Jandus" and "Westminster"

sed arcs, and the mercury vapour light, the use of all which lights printing as well as for portraiture they demonstrate to their visitors. Not only that, the premises, as our two photographs show, equipped with cameras, backgrounds, head screens, etc., and the photographer is given every facility to bring his own lens and paper make his exposures and develop his plates on the spot. Similarly can, if he wishes, have the opportunity of printing off a few negatives from his own negatives on his own printing-out paper in order acquaint himself with the possibilities of artificial light printing as offered by Messrs. Griffin. In fact, the firm's great aim is to keep the department up to date in matters of electric light-photographers.

Other branches of professional work are likewise the object of demonstration. The dry-mounting process is made a feature, and in way of backgrounds some novelties are to be seen. The

verside" ground, of distinctive character, is one of a brought out by Messrs. Griffin to provide the photographer, at moderate price, with the effects he obtains in the most expensive African grounds. With respect to mounts, too, Messrs. Griffin file the beautiful Collins series, but they have also other series of their own, among which we saw enough taste and variety to prove that the photographer can find excellent opportunities for wise selection. Of studio furniture we notice with satisfaction some desks in fumed oak which look well, photograph well, and give an air of reality to the studio. All these and other new introductions of the firm are gladly shown to bona-fide professional photographers, for whose use solely the department is set apart. The hours during which it is open are from 9 a.m. to 6 p.m.

#### PHOTOGRAPHY AT THE FRENCH PHYSICAL SOCIETY.

(From our Paris Correspondent.)

PHOTOGRAPHIC and optical appliances were well represented at the annual exhibition of this Society, held in their rooms opposite the Palais des Près, although no striking novelties were to be seen. The exhibition partook very considerably of a commercial show, the striking and interesting experiments which attract one at the meetings of the Royal Society do not enter into its scope. Passing to the left, one would have expected to see photo-telegraphy more to the fore, considering the variety of devices for that purpose suggested in the past year. Actually only a full-sized model of Prof. Korn's installation and a small model of Carbonelle's "Télé-aveur" were to be seen. The latter is an instrument similar to a camera, and utilising a carbon relief, the variations of which are turned into changes of electrical resistance by a microphone. Mr. Richard exhibited the latest forms of their well-known camera, beside instruments for determining the speed of light and for photo-chronographic registration.

M. E. Estanave showed examples of a method of giving an appearance of relief to transparencies, which consists in simply

placing in contact with them a line screen of about three to four spaces to the millimetre. Viewed at some 40 cms., a very agreeable stereoscopic effect is obtained.

A direct reading photometer was shown by Prof. Ch. Féry, based on the following principle:—If from a given light-source that quantity only of each monochromatic radiation proportional to the sensitiveness of the retina for that radiation is allowed to pass, then the heating energy of the total flux obtained is proportional to its luminous intensity. This may be secured by limiting, with a screen of appropriate form, the height of the spectrum, and then reuniting the radiations. In practice it is simpler to use a copper acetate screen which in sufficient thickness cuts off the infra-red. The radiation is then allowed to fall on a radio-micrometer, in which two thermo-junctions are heated alternately by the beam passed through a lens moved at a distance by pneumatic releases. A Carcel lamp—about 10 candles—gives at 1 metre a deflection of 60 mm.

In colour photography Messrs. Calmels exhibited a stand of Wratten and Wainwright's colour screens. Some very good Autochromes taken by Messrs. Lumière were projected, and M. Rothé, Professor of Physics, at Nancy, showed spectra obtained by an interesting modification of Lippmann's process, in which the mercury surface is dispensed with, the stationary waves being obtained by reflection from the air-surface. His plates are prepared with a double layer, the sensitised layer being coated on a second layer of plain gelatine. Prof. Rothé has made a detailed study of the various interference fringes occurring with polychromes prepared thus, with a view to obtaining the colours free from disturbing secondary effects. It will be remembered that a cause vitiating the purity of the colours in Lippmann photographs has been the reflection of light from the surface of the gelatine layer, the white light not only causing mixed colours, but selected waves, by interference with the actual waves (Tiefenwellen) from the colour-forming layers in the film, altering the colours. These surface waves were removed by O. Wiener by deviation, a thin glass wedge being cemented on and the polychromes viewed in a plan parallel trough filled with benzole. Prof. Rothé shows preparations by his method with the coatings in a wedge of variable thickness. Examined in monochromatic sodium light, they showed three systems of fringes, first Newton's colours of thin plates, secondly, surface waves or Wiener's fringes, and thirdly fringes parallel to the spectral rays. He finds that the Wiener fringes, as seen from the glass side, may be avoided by a suitable thickness of gelatine or a double layer. The spectra shown, if not as brilliant as some of Lippmann's specimens, or some shown by Lehmann of Jena, were of great purity. Sections made with the microscope showed a large number of silver lamellae. Prof. Rothé stating he has counted up to thirty, and that his studies in this, shortly to be published, lead to several different conclusions from those of Cajal.

ROYAL INSTITUTION.—On Thursday next (May 21), at three o'clock, Dr. Alexander Scott will deliver the first of a course of three lectures at the Royal Institution on "The Chemistry of Photography."

PHOTOGRAPHY IN TURKEY.—According to a report of the French Chamber of Commerce at Constantinople, the photographic trade in that capital is brisk and a large number of studios have recently been opened. The demand for apparatus and accessories of all sorts is good, more especially for the cheaper qualities. Amateur photography has become popular of late, and trade in apparatus and accessories is satisfactory and is increasing. A large number of amateurs have their plates developed and the pictures printed by professionals. A considerable amount of the trade in apparatus and accessories is in French and German hands, but the report says there is a fair demand for Paget English paper. Sensitised papers ("Solio" and "Platino Matt") placed on the market by the Kodak Co. have a good sale. The French Chamber speaks in high terms of the way in which the Germans push their goods by endeavouring to meet the wishes of the customers in every possible way, and by systematic advertising campaigns, and the Chamber expresses the opinion that to follow the methods of the Germans in this regard is the only way the manufacturers of other countries can hope to hold their own and increase their trade.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been made between April 27 and May 3:—

**TRIPOD ATTACHMENT.**—No. 9,271. Improved means for securing easels, camera stands, and other similarly portable articles to the ground. Winsor and Newton, Ltd., and Henry Bowser Wimbush, 17, London Road, Wembley, Middlesex.

**SILVER PAPERS.**—No. 9,275. Improvements relating to silver photographic papers. August Zimmermann, 24, Southampton Buildings, London, for Chemische Fabrik auf Actien vorm. E. Schering, Germany.

**APPARATUS.**—No. 9,349. Improvements in and relating to photographic apparatus. Alchanan Cohen, 69, King Edward Road, Hackney.

**CINEMATOGRAPHS.**—No. 9,404. Method of and means for showing cinematograph pictures with coloured backgrounds. Ernest Osman Brown, 53, Chancery Lane, London.

**STEREOSCOPE.**—No. 9,507. Improved stereoscope. Karl Lenck, 40, Chancery Lane, London.

**PHOTO-TELEGRAPHY.**—No. 9,518. Improvements in the electrical transmission of half-tone or line photographs. Thomas Thorne Baker, 12, Whitefriars Street, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**CINEMATOGRAPHS.**—No. 23,396, 1907. The invention consists of apparatus for photographing and exhibiting cinematograph views of a panoramic form to include the entire horizon or any desired angle of it, the pictures to be photographed in sections, each including about 36 to 45 deg. of the horizon, and to be projected by a lantern on to a cylindrical screen, in the centre of which the lantern is fixed.

For segmental views, including only from one-fourth to one-third of the horizon, the pictures are taken on a film wide enough for two or three pictures side by side, each picture being a segment of the horizon of about 36 to 45 deg., which are projected on to the film by separate lenses placed at similar angles radially. To receive the pictures at right angles to the lenses, the film may be bent horizontally by passing through rollers, or if not bent, prisms may be used to bend the rays of the pictures to the required angle.

To take and to project pictures to include the entire horizon, or more than one-third of it, the same apparatus must be employed in duplicate or triplicate, each film to take its own two or three sections of the horizon, which is divided into about eight or nine sections, and for projection must be arranged radially around a central light, or separate lights may be employed for each apparatus. Thomas Walter Barber, 82, Victoria Street, Westminster, London, S.W.

**CERAMIC PHOTOGRAPHS.**—No. 24,214, 1907. The invention consists in (1) the use of a sensitising solution of honey or other sugar, nitro-cellulose dissolved in ether, or acetone with alcohol or other liquid, rendering the ether or acetone miscible with water and ammonium or potassium bichromate. (2) Coating with this solution, exposing under a transparency, applying a powder, washing and fixing to fix the colour.

The proportions of the constituents of the solution are of great importance, and are indicated by the following example:—

100 c.c.s. collodion solution (composed, for example, of 250 c.c.s. ether, 250 c.c.s. methylated spirit or alcohol, and 4 grams guncotton).

100 c.c.s. methylated spirit or alcohol.

2 grams ammonium or sodium bichromate.

4 grams honey or other soluble carbohydrate, about 5 c.c. water.

The powdered bichromate and the honey are preferably dissolved in the water slightly warmed, the spirit added, and then the collodion solution.

By sensitising the desired surface with this solution and exposing it under a transparency, the latent image obtained is taken up the powdered pigment or colour perfectly, and reproduces every detail and shade of the transparency.

When the surface thus treated with colour is washed with water, the carbohydrate and bichromate are at once entirely removed without in any way displacing the pigment, which is retained on the surface by the uniformly distributed collodion. The surface can then be at once fired to fix the pigment. The direct reproduction of the original image may thus be obtained.

The glass, porcelain, enamelled metal, or other surface is coated with an even film of the sensitising solution and dried, preferably by a gentle heat until the surface ceases to be adhesive to an object placed in contact with it. The image or design is then placed in contact with the sensitised surface and exposed to light.

After exposure the surface may be gently warmed for a few minutes, and a suitable pigment or colour is then dusted on and may be rubbed in with a brush. The powder will adhere to the film inversely as the action of the light has taken place. Thus it will attach itself to those portions of the surface corresponding to the dark portions of the original. The surface is then washed with water, whereby the soluble matters in the film are dissolved and removed, leaving the image in pigment or colour there. The surface is then dried and fired.

The invention may be applied to the reproduction of images of wood, metallic, or other surfaces in cases where it is not desirable to fix the image by firing. In such cases, when the surface is porous it should be enamelled or coated with a suitable ground to prevent absorption of the sensitising solution. The picture may be protected by varnishing or other suitable means. Manufacturers, 13, Fitzroy Street, and Edwin Lloyd, Limited, of Newman Street, Oxford Street.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

**CINEMATOGRAPH.**—No. 8,963. Means for displaying animal pictures or the like. De Mare.

### New Trade Names.

**EVANITE.**—No. 301,299. Photographic apparatus included in Clay in metal and earthenware. Evans, Sons, Lescher, and Weller Limited, 56, Hanover Street, Liverpool; and 60, Bartholomew Close, London, E.C., wholesale druggists and photographic manufacturers and dealers. March 13, 1908.

**ARTURA.**—No. 299,215. Photographic developing and printing paper. The Artura Photo Paper Company, 1,500, Eastway Avenue, Columbus, Ohio, U.S.A., photographic paper merchants and manufacturers. January 1, 1908.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Development Made Easy.

"I have pretty well completed" (says Mr. Alfred Watkins, writing in "Photography and Focus" of May 12, of a new developer which his firm has just worked out) "a test of all the plates and films, development speed of each, and shall in future give this on the score card, in addition to exposure speed. The variation of time for different plates is very striking. I divide plates into seven groups, two and a quarter minutes being the average time, at 60 deg. F., with my developer for the quickest group, and eleven and a quarter for the slowest group. Of course, this can only be taken as approxi-

mate, as makes are not always uniform. The groups will be given by letters VQ, Q, MQ, M, MS, S, and VS, and the information will, I think, be useful to those who do not buy my developer. I expect to have it out in a month, as all plant and materials are ready. I have in preparation an adjustable thermo-calculator, for developers of different temperature co-efficients, to be made in metal."

### The Ozobrome-Oil Process.

This process (writes Mr. J. Parrack in "The Amateur Photographer and Photographic News" for May 12), which should prove of considerable advantage to workers in the oil-pigment and Bromoil processes, enables the operator to obtain any number of oil prints from single bromide (or gaslight) print. In practice it is a combination of the ozobrome process and oil printing. The bromide print is prepared in the same way as for ozobrome. Place the bromide print in clean, cold water. Next take a piece of oil pigment paper (or any other paper suitable for oil printing) and wet it in cold water. Then place it in dilute ozobrome solution, made by adding four parts of water to one part of concentrated solution. Allow the paper to remain in the solution two minutes. Lift it out and drain off the superfluous solution. Now draw the paper through clean water and bring it into contact with the bromide print. Take the two papers and squeeze them into close contact. Leave for about twenty minutes. When this time has elapsed place the prints in clean water and separate. So far the working has been the same as the ozobrome process, except that instead of pigment plaster oil-pigment paper has been used. The rest of the operation is the same as in oil-printing. Wash the paper to get rid of the ozobrome solution. Place the paper on the wet blotting pad, surface dry, and then may be developed up with any suitable developer. It is then dried and kept for further use. The oil print will, of course, be reversed, but as this process would be used principally in the case of enlargements, this is no drawback. If the operator, in making bromide enlargements intended for this process, reverses his negative he will obtain from it any number of oil prints the right way round. There appears to be no limit to the number of prints obtainable.

### New Books.

*Le-Mémoire Pratique de Photographie.* By L. P. Clerc. Paris: J. B. Baillière et fils. 4 francs.

This volume is a revised edition of the text-book by M. Albert Clerc, which for some years past has appeared under the above title. M. Clerc in re-preparing it for the amateur worker, has strengthened the portions dealing with lenses, shutters, and such important, but often disregarded, questions as principles of perspective, distortion, and depth of focus and field. In short, optical matters concerned in the making of a negative come in for a far larger share of notice than is usually the case in text-books. Processes of development and of positive printing are dealt with fully. M. Clerc, who contrives to write for the non-scientific reader in a way not to mislead him. Chapters on stereoscopic and colour photography conclude a very excellent text-book.

**ELECTRICAL INDUCTION-COIL CONSTRUCTION.**—Messrs. Percival Marshall and Co. have published a shilling manual on this subject, the pen of Mr. J. Pike, an old contributor to the "British Photographer," and a practised hand in electrical construction. Mr. Pike writes explicitly of the details and methods of building and winding spark coils, and his book should be of real value to those who employ such apparatus for X-ray or other purposes.

**EDINBURGH "COMPETITION."**—Messrs. John J. Griffin and Sons, Ltd., announce the offer of prizes of £3 3s., £2 2s., and £1 1s., in addition to consolation awards of 5s. each, for prints on their "Gold-softening paper." The contest is open only to amateur photographers who have hitherto not been successful in any competition.

### New Apparatus, &c.

The "Ensign" Signal Clock for Time Development. Sold by Houghtons Ltd., 88-89, High Holborn, London, W.C.

Messrs. Houghtons have here produced a dark-room clock with several good points of specially practical importance. The clock is made for signalling by an alarm bell of long or short duration, the expiration of any period of time from one minute to one hour. The design is ingenious. The act of setting winds the clock. All that is necessary is to insert the key in the centre of the dial and thus turn the finger downwards (to the right) from the sixty position. It can

remain in this set position for any length of time, and is started on its period by touching a lever on the right-hand side of the dial. The finger then returns to the 60, and on reaching it sounds the alarm. If for any reason the operation which is being timed has to be interrupted, the clock can be stopped at once by the right-hand lever and restarted when required.

The alarm adjustment, as we have just said, is a good feature of the clock. It can be made to give a short, sharp ring-ting, or wound so as to sound a prolonged signal. The dial of the clock is bold and clear, the instrument conveniently mounted for hanging in the dark-room, and the price 12s. 6d.

### New Materials, &c.

**"Albumat" Printing Paper.** Sold by Charles Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London, E.C.

As its name indicates, this new paper, which is one of the brands long issued by Messrs Zimmermann under the trade mark of "Crossed Swords," owes its special qualities to albumen, and is in fact a modern revival of the matt albumen paper of more than forty years ago, with the important differences, however, that it is supplied in a sensitive condition ready for use, and is obtainable in a number of extremely beautiful surfaces, far exceeding the quality of those which printers of the sixties and seventies had at their disposal. Albumat, though an albumen paper, has nothing in common, as regards appearance and working, with the later albumen paper of the semi-glossy kind, i.e., the albumen process as it is worked at the present time. It is a paper of a quite matt or natural surface resembling a photogravure print as much as anything else, and, moreover, it is amenable to the production of a variety of very fine tones by the use of the gold and platinum baths, now customary in the manipulation of collodion-chloride paper. Thus, the paper does not involve the tendency to blister in the baths or crack in the final stages for the simple reason that the albumen vehicle of the silver salts is so conveyed into the substance of the paper that the handling of the prints is precisely that adopted in the case of plain salted paper. The difference in keeping quality of "Albumat," however, will be understood when it is stated that the makers guarantee it to remain ready for use for at least four months.

So much for the general properties of the new paper. The manipu-

lation can be described in a few words, and we can then pass to consider the various admirable varieties which are obtainable. A fine range of tones from warm brown to blue-black and black are produced by (1) Simple gold toning; (2) Platinum toning alone; or (3) Gold toning, followed by platinum. The recommended baths are:—

Water .....	20 ozs.
Acetate of soda .....	22 grs.
Carbonate of soda .....	4½ grs.
Chloride of gold .....	1 gr.

or

Water .....	20 ozs.
Sodium tungstate .....	3 grs.
Borax .....	45 grs.
Chloride of gold .....	1 gr.

and

Water .....	30 ozs.
Chloroplatinite of potassium .....	15 grs.
Phosphoric acid (1.120 S.G.) .....	½ oz.

which are used pretty much as with collodion papers, except that toning is very much more rapid than with papers of this class, and on this account care must be taken not to over-tone.

Exactly a dozen different varieties of "Albumat" are offered, all of a kind which are particularly fitted for the purposes of the professional photographer. The characteristics of these papers are not easily described, and therefore we may advise the purchase of the sample packet of one piece (6 x 4½) of each grade. We may, however, speak of the effect, as we see them in prints which we have made on these various descriptions of "Albumat." "Smooth," "fine grain," and "coarse grain" are the titles of three distinct surfaces of the paper. The first is a quite smooth paper, yet with the beauty of its natural surface. Nos. 1 and 2 are a thin and thick paper of this class, and No. 3 is a thick but cream paper of the same surface. The next degree in roughness of surface is the "fine grain," fine enough for cabinet work of the bolder kind, and very suitable for larger portraits. It is represented by Nos. 4 and 5, white and cream respectively. The rougher "coarse grain" (Nos. 6 and 7, again white and cream) is not a very rough paper. Both varieties are thick paper, eminently suited for the folder method of production, owing to the substance and flatness of the prints. The remaining five papers (Nos. 8 and 9) are white and cream varieties of a so-called "bank" paper of peculiar pebbled surface, giving an effect which is bold but distinct from the roughness of Nos. 6 and 7. The "half-tone" white and cream (Nos. 10¹ and 10²) possess a structure somewhat resembling a half-tone print, and are among the papers which most attract us from their novelty and delicacy, though the result of printing on them is perhaps harder to describe than in the case of any other of the papers. Lastly we come to No. 11, a Japanese vellum Albumat-sensitised, and with all the beauty of the material.

We have said enough, we believe, to show our professional readers in particular that the twelve varieties of "Albumat" supply the means of producing a number of attractive styles of photographic portraits, and that a trial of them should repay the photographer who is anxious to convince his customers of his ability to offer them something both excellent and different. We need only add that Nos. 2, 5, 10¹, and 11 are put up in packets, and that all the other brands are stocked by Messrs. Zimmermann in sheets at prices which vary from 25s. to 35s. per quire. Full particulars of the prices and sizes of the sheets are given in the "Albumat Circular."

**STUDIO DECORATION.**—Messrs. F. E. Jones and Co., of 22, Gray's Inn Road, London, W.C., have sent us some photographs showing studios decorated by themselves for several well-known photographers. Messrs. Jones make a special feature of the tasteful use of oak panelling, and the effect obtainable by this simple and not very expensive method certainly should encourage those who are anxious to give a handsome appearance to their establishments to put themselves in communication with Messrs. Jones. Photographs, such as we have before us, give a very fair idea of the effect obtainable, and Messrs. Jones are ready to give an estimate from plans of the rooms in which the work is to be done.

**BUSINESS BAROMETERS.**—Messrs. W. G. Systems, Ltd., of Craven House, Kingsway, London, W.C., send us specimens of the squared sectional paper issued by them for the charting of business returns,

expenses, profits, or other business moneys or items in a form which admits of variations being seen at a glance. The paper is ruled for daily, monthly, or three-monthly use, and the advantages of the material to both technical and business managers are sufficiently obvious to us to recommend inquiries, for samples and particulars to the W. G. Systems, Ltd.

## CATALOGUES AND TRADE NOTICES.

**THE TELLA CAMERA Co.**, of 68, High Holborn, London, W.C., have issued a list of second-hand and reduced apparatus and accessories which includes a large variety of hand and stand cameras, lenses, enlargers, lecture lanterns, etc., all of which the firm guarantee to be in perfect working order. The prices appended to the various items seem to be exceedingly reasonable, and photographers desirous of making changes in, or adding to, their photographic outfit would do well to procure a copy of this list of bargains from the above address.

**ENLARGING AND PRINTING.**—E. W. Bowes and Co., 16, Ethelred Road, Shepherd's Bush, London, W., have issued a very clear printed price list of their enlarging and printing work in bromide, carbon, platinotype, and of other trade work done by them. Messrs. Bowes undertake large and small commissions for professional photographers, and their electric plant enables them to guarantee prompt delivery. The list is sent free to bona-fide readers of the "B.J."

**RETOUCHING AND MINIATURE PAINTING.**—Mr. G. R. Henderson, 16, Ellison Street, Hebburn-on-Tyne, sends us a card of prices for miniatures on ivory-carbon prints, from photographers' negatives. The prices are moderate, and the work, as we expect of Mr. Henderson's studio, of high quality. The miniature being a profitable item in the photographer's, there is good reason to become acquainted with the firms making a special feature of its production.

**ROSS, LTD.**, 3, North Side, Clapham Common, London, S.W., have just issued an abridged list of lenses, cameras, and other apparatus of their manufacture, as fitted by them with one or other of the optical attachments. The list includes particulars of the large aperture lenses made by this well-known firm.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, MAY 16.

Liverpool Amateur Photographic Association. Excursion to Llangollen.  
South London Photographic Society. Excursion to River Thames.  
Manchester Amateur Photographic Society. Ramble to Haigh Plantations.  
Haigh Hall, Wigan.  
Chelsea and District Photographic Society. Excursion to Greenford.

MONDAY, MAY 18.

Harrow District Photographic and Scientific Society. Demonstration, Kodak Limited.  
Bowes Park and District Photographic Society. "The Wonders of the Heaven as Revealed by Photography." C. P. Butler, A.R.C.Sc., F.R.P.S.  
South London Photographic Society. "Further Notes on the Oil Process." A. R. F. Evershed.

TUESDAY, MAY 19.

Royal Photographic Society. "Some Examples of Architecture in Ireland." Chas. H. Oakden.  
Hackney Photographic Society. "Lantern Slide Making." F. E. Roope.

WEDNESDAY, MAY 20.

Tunbridge Wells Amateur Photographic Association. Members' Lantern Evening.  
Central Technical College Photographic Society. "Some Points in the Development of a Photographic Objective." Val. H. Mackinney and H. C. Patey.  
North Middlesex Photographic Society. "The Use of Apparatus in the Field." H. Stuart.

THURSDAY, MAY 21.

Optical Society. "Telemeters." J. Cheshire.  
Midlothian Photographic Association. "Architectural Photography." E. Brown. "One Man Show." R. M. Readdie.  
North London Photographic Society. "Handwork on the Negative." J. Rattle.  
London and Provincial Photographic Association. "The Donisthorpe Process." Frank Donisthorpe.  
Harrow Photographic Society. "Printing by the Donisthorpe Process." F. E. Bill.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held May 12, the president, Mr. J. C. S. Mummery, in the chair. The Chairman announced that Mr. John Sterry, in consequence of taking a voyage to the Antipodes, had been compelled to resign the treasurership of the society. The council had elected Mr. Leslie E. Clift in his place, and had filled the vacancy thus created on the council by electing Mr. C. H. Oakden.

It was announced that the following had been elected Fellows of the society: Herr R. Dührkoop, Dr. Lindsay Johnson, Mr. Thomas Anny, Mr. Harry E. Smith, and Mr. K. J. Tarrant.

Mr. Furley Lewis gave a short address as introduction to a new exhibition of portraiture by himself. He explained that the portraits on the walls were not made for exhibition, but were portraits of mere men done by him in the ordinary way of business. His aim had to be, first, a likeness of his sitter, and he had further made it his study to obtain prints which represented the good qualities of photography as a medium. Mr. Lewis's short, but interesting, address was much enjoyed.

Mr. Frank Donisthorpe then gave a demonstration of the process of printing his name, already described in these pages. He explained the method of treating a negative to absorb a dye in the undyed portions, and showed the production of prints by contact without light from a negative treated in this way.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held on Thursday, May 7, Mr. R. Beckett in the chair. Mr. T. Wilkinson described a method of making a negative from a positive as follows. He took a negative and printed it in a printing frame, upon either the slow negative paper as issued by the Rotary Company, or the Wratten slow plate, giving the exposure required to make a positive. This was then developed in an M. Q. developer, rather darker than it would be in the case of the positive, washed. After washing it was exposed to light under water until the Watkins meter registered one tint, and then bleached in the following bleaching solution:—

Potass bichromate .....	150 gr.
Nitric acid .....	1 dr.
Water .....	10 oz.

It was washed, and given two baths of the following, in order to remove the bichromate stain:—

Soda sulphite .....	1 oz.
Potass metabisulphite.....	15 gr.
Water .....	10 oz.

The plate was redeveloped in the M. Q. developer. Wash and fix in an acid bath, and finally wash and dry. This, he said, gave a reversed image suitable for carbon printing, for an ordinary negative the same should be made in the camera. Enlarged negatives could, however, be easily and cheaply made by the method. He passed round slides and prints by the process.

Mr. Haddon suggested that sulphurous acid in the clearing bath did not do the work just as well and be cheaper, and he asked why the Wratten plate gave good results, whilst other brands of plates did not.

The lecturer said that he had used some seven or eight brands of plates and they all fogged in the second development. Mr. Haddon thought that this might be due to the fact that the one plate was developed with pure silver bromide whilst the other was made with iodide of silver; but Mr. Wilkinson said that he had obtained good results with wet plates.

Mr. Haddon said that the iodide could not be the cause of the fog, as the wet plates it would be present. He thought that a pyro developer would give good results, the lecturer's statement to the contrary notwithstanding.

Mr. Teape had worked a similar process for making reversed images and obtained good results upon three or four brands of plates, but with the faster brands even of the same maker he found that fog resulted. He had put this down to the presence of iodine.

BROMOIL EXHIBITION.—The present exhibition of bromoil remains open at the "British Journal" house until Wednesday, May 27. It will be re-opened on Monday, June 1, at the "Levee" of Messrs. John J. Griffin and Sons, Ltd., Kingsway, the pictures can be seen until June 20.

## Commercial &amp; Legal Intelligence.

CANVASSING FRAUDS AT LEICESTER.—Last week, at Leicester, Ernest Lay, a porter, was brought up on remand charged with obtaining 6s. by false pretences from Lily Gibbons, on April 2; further on obtaining 2s. from Louisa White on April 28; and 8s. from James Hender Harris on April 3 and 4, also with intent to defraud. Evidence was now called in the last two cases, the allegation being that prisoner represented himself as in the service of the Fine Art Association, Derby, and obtained money on account of photographic enlargements, when he had not been in the direct employ of the association at all, and was not authorised to collect accounts. He had been occasionally engaged by a collector of the association to carry parcels. Prisoner pleaded guilty, and the Chief Constable stated there were five previous convictions against Lay, there being also twenty-six other charges of a similar nature to the present.—In each of the two cases dealt with prisoner was sentenced to three months' hard labour, six months in all.

CANVASSING CASE.—A photographer's canvasser named William Richard Meare was charged at Barnsley last week with having obtained 6s. by false pretences from a Cudworth miner named Charles William Hayes on March 26 last. Defendant was employed as a canvasser by the American Fine Art Association, and on the date named he took an order for an enlargement from Hayes, receiving 6s. as deposit, together with a silver Albert and two medals, which he took on the representation that they were necessary for the proper completion of the picture. No picture was forthcoming, and it was afterwards found that the chain and medals had been pawned at Wombwell.

## NEW COMPANIES.

LONDON NEWS AGENCY PHOTOS., LTD.—Registered April 24. Capital, £1,000 in £1 shares. Objects: To carry on the business as a news, photograph, and commercial photograph agency, but not any business competing with that of the London News Agency, Ltd. No initial public issue. Registered office, 46, Fleet Street, E.C.

## News and Notes.

LECTURES ON PRINTING PAPERS.—A course of three lecture demonstrations on "Papers for Printing" is being given at the Bolt Court School on Thursday evenings from May 14 to 28, 1908, inclusive, by Mr. R. W. Sindall, F.C.S. The syllabus for the two remaining lectures is:—Paper for magazine printing; the suitability of esparto and wood pulp for these papers; their manufacture; points to be studied by printers—register, surface, bulk, transparency, discoloration, and other qualities; paper for half-tone printing; the manufacture of "art" paper; the causes which have led to the use of a coated paper; precautions necessary in printing; the durability of the illustrations. All lectures commence at 8 p.m.

PICTURE POSTCARDS.—At a recent meeting of the German Geographical Society the idea was advanced, for the first time, to employ picture postcards as means of instruction in the schools. The postcard industry has made enormous progress in the last few years, and in the last few months cards have been brought into the market, illustrative of natural history, political history, and for use in instruction in the German language, which have met with the hearty approval of professors and teachers of repute. According to the American Consul at Magdeburg, the school museum at Breslau has undertaken to form a collection of these cards, and for this purpose the authorities have requested the various publishers to forward them samples of their output, that it may be determined to what extent they may be used for purposes of instruction. Further, two teachers in Leipzig have established a central bureau for postcards of all sorts, intended for purposes of instruction or collection. They have also developed, and offered for sale, two practical systems for the display and filing of the cards. These gentlemen select and arrange the cards most carefully, according to pedagogical principles. Such prominent educationalists as Harms, Tischendorf, Rudolf Schmidt, and others have

endorsed the plan of using illustrated cards as an aid in instruction, and even official bodies anticipate favourable results from them.—*"Journal of the Society of Arts."*

THE SUBURBAN AND PROVINCIAL DEVELOPMENT ASSOCIATION, of 29, John Street, Bedford Row, London, W.C., have added illustrated guide books dealing with the districts of Chichester, East Grinstead, Horsham, Lewes and Seaford to the series which they are issuing as useful suggestions to those who may be desirous of either changing their place of residence, or of selecting cottages, etc., for week-end visits. Copies of the booklets, which are well illustrated and contain much useful information concerning the districts of which they treat, may be had, post free, by applying to the respective town clerks.

THE AFFILIATION COMBINED OUTING will take place on May 23. The rendezvous will be at Ayot, near Hatfield, on the Great Northern Railway. Tea will be provided at the Red Lion Hotel, Digswell Hill, at 6.30 prompt. Tickets, 1s. 3d. each, can be obtained from the Acting Secretary, Mr. H. Philp, 66, Russell Square, W.C. Day excursion tickets at a fare and a quarter, 2s. 3d., can be obtained at King's Cross and Finsbury Park Stations by the trains leaving King's Cross at 1.15 p.m. and 2.30 p.m. Members of the North London Photographic Society (distinguished by a white rosette) acting as stewards will be in attendance by the Booking Office at King's Cross and Finsbury Park, and also at Ayot, to furnish any information that may be required.

## Correspondence.

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### EXPOSURE IN ENLARGING.

To the Editors.

Gentlemen,—In your note of May 1, on "Exposure in Enlarging," you assume that my rule of exposure is "a theory worked out on paper," and that alone. I can assure you it is the result of some thousands of adjustments and some hundreds of exposures with a gradometer, using three different enlargers during the past three years. One, a "Koresco," I tested for daylight enlarging, and found the ratio of exposure to be as I state. It was after I had found this experimentally that I worked out, mathematically on paper, the proof that it should be so. Then I tested for gaslight exposures with the same enlarger, fitted with incandescent light attachment (Welsbach mantle), and an 8½ in. condenser, and using a quarter-plate gradometer. I found that with certain adjustments I got the same ratio of exposures, and then proceeded to work out, mathematically on paper, the reason why. The projector used in that enlarger was the ordinary cheap lens, working at  $f/16$ , and the aperture was smaller in diameter than the conjugate image of the incandescent light formed by the condenser up to a 15 x 12 enlargement. Then I tried it with a Dallmeyer stigmatic lens, working at  $f/6$ , with the same result. Next I took a cheap combination lantern, with 5½ in. condenser, and later a similar lantern, with 5 in. condenser, fitted to take a Sanderson quarter-plate camera. These I also tested, using the same Dallmeyer lens as projector. The conjugate image of the incandescent light was larger than the aperture up to a 15 x 12 enlargement. When adjusted for a 21 x 16 enlargement the full aperture was larger than the evenly illuminated portion of the conjugate image of the light, and the disc at full aperture was not evenly illuminated. I stopped down to  $f/8$ , and the disc was then evenly illuminated. I continued to stop down to  $f/16$ , and there was still even illumination. Then as I continued to stop down illumination fell off. At the smallest aperture the illumination was bad. But I also noticed that in the centre of the conjugate image of the light there was a perpendicular bar of com-

parative darkness with a forked top, obviously the image of the support which carries the mantle. I am afraid to suggest that this might have something to do with the uneven illumination at the aperture. Hence in writing last week I was careful to suggest that the writer of the "Ex Cathedra" note should stop down until he got even illumination only, not indefinitely. I regret that I guess as to the aperture he used was incorrect. But I think he will find his Sin. R.R. working at  $f/8$  also transgressed the essential condition of my "theory," and that the diameter of the work aperture was greater than the diameter of the evenly illuminated portion of the conjugate image of the light. If he stops down until the evenly illuminated portion of the image just covers the aperture he ought to get even illumination of the disc. I get it with my lantern. If he does not get it with his it must be the fault of the lantern, not the fault of the "theory."

With regard to the case of small and powerful lights, I do not see that my rule of exposure will hold good for any light and any lantern. I suggest it will, under the conditions laid down. But at present my anticipations in that respect is a "theory," though "theory" which I hope to prove by practical demonstration in the case of Nernst and arc lights, as I have proved it in the case of the incandescent mantle.—Yours faithfully,

JOHN NIXON.  
Rydal, Ingleside Grove, Blackheath.

## Answers to Correspondents.

*\*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

*\*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*\*\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 2A, Wellington Street, Strand, London, W.C.*

*\*\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C. undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, &c. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- J. H. Smith, 1, Waller Hill, Skipton, Yorks. *Photograph of Skipton Militia Band.*
- Mrs. H. C. Sutherland, Cooleville, Clogheen, Cahir, County Tipperary. *Photographs of Kittens.*
- E. R. Yerbury, 1, Hanover Street, Edinburgh. *Two Photographs of the Lord C. J. Guthrie.*
- G. H. Morgan, 90, Shakespeare Street, Southport. *Photograph of Carlisle United Football Club, First Team, 1907-8.*
- H. Watson, 435, Langsett Road, Sheffield. *Photograph of a Combined Photograph and Drawing of the New Soldiers' Home, Langsett Road, Sheffield.*
- J. W. Fyfe, 27, Whitcombe Street, Aberdare, Glamorganshire. *Photograph of Welsh International Association Football Team, 1907 and 1908.*
- J. L. Hart, 52, Nantwich Road, Crewe. *Two Photographs of Wm. E. Harris Professional Footballer.*

Owing to the demands on the space in this section, a number of replies are held over until next week.

B. E. W. (Bradford).—Thanks for letter. We shall have something to say on the subject shortly. You can plate-mark prints in an ordinary rolling press in this way. Get a metal plate the size required and place it on the bed of the press. Place the mounting print in position on it, and on that lay two or three thicknesses of printers' blanketing, and pass the whole through the press. This will give you a very good plate mark.

PUTTY FOR GLAZING STUDIOS.—Will you kindly give me the name of the firm who supplies putty for glazing studios—it does not do

! You mentioned it some years since in the JOURNAL, but I not trace it.—NERO.

"We have no recollection of the name of the firm mentioned me years since." However, in practice, nothing is better than nary putty, if it is made with good raw linseed oil. We d advise you to make it for yourself, as that sold at the oil s is often made with common cheap oils, not linseed. It is necessary to knead whiting with the oil to the consistency ired.

BROMIDES.—I have an order in to print and tone a batch of ide cards similar to enclosed. Could you oblige me by letting know, through your journal, process of toning. I am in the t of using the sulphide process, but find the colour much r than sample.—BROMIDE.

ie tones vary a good deal with different papers, but we should hat you can get a tone such as that of the card you send by hypo-alum method, which is that largely used by commercial urers of cards.

QUERY.—Enclosed please find rough sketch of a building ally built as a carpenter's workshop. As it is now unl thinking of converting into a studio. I would be glad to y your suggestions re lighting, especially if you think a top is necessary, and also if you would block up any of the three ews, and which? As you will see, the windows all face west, ll have to reglaze with ground glass. Could the place be used e modern style without top light, or is top light imperative? modern style, what alterations in lighting would be necessary? ide windows are three in number, each measuring 90 inches 0 inches high, and come to within 3 feet of floor. There is a foot of brickwork above windows to get to the slate ing. I would be glad if you would let me have a reply to n the next issue of "B.J."—H. J. LE BRUN.

the sketch shows the side light to the ridge of the building so low we do not see that you could get standing figures evenly d. We should suggest that you introduce some top light, y glazing part of the roof, half the slope, commencing five feet from the south end, and ending about 14 feet from end. The foot of brickwork above the windows had better moved when making the alterations, as that, if left, would up the light at an important part.

P.O.P.—Nearly all P.O.P. and postcard makers advise when g with the sulphocyanide bath that the prints be well d to get rid of all free nitrate. I should be glad to have opinion on this advice. My experience is that such is pre al to the toning. The longer the wash the worse the results. t, one of my friends does not wash at all.—DELTA.

believe that all who have investigated the toning of silver are agreed that the silver nitrate should be washed out. a we are not prepared to say why this washing should be ary before the sulphocyanide bath. We are inclined to that others' experience is contrary to yours, and that many wash the prints because they consider the washing to e the ultimate tone. A good tone is more or less a matter onal opinion.

—The best reply we can make to your queries is to sug at you send your young friend one or two copies of the " from the small advertisements in which, on pages ii. and e can judge better of her prospects here than in any other

ING PAPER.—Will you please give me a formula to make ing paper, glossy or matt, and if the same formula will cream crayon paper. I am experimenting on a small coat-chine, and would like to try a self-toning paper.—W. C. ula are to be found only in patent specifications, and we no more than refer you to recent issues of the "Almanac," abstracts of these latter have appeared, viz., 1906, p. 816, 07, p. 785.

ENOL.—I thank you for diamidophenol formula in this "B.J." (1) Will this keep in a well-stoppered bottle; is the bisulphite, which I saw in a formula as "liquid ite," metabisulphite or sodium bisulphite?—H. S. P. C. es, it will keep in the strong stock solution for a fairly

long time. (2) Sodium bisulphite,  $\text{NaHSO}_3$ . Metabisulphite is a different substance.

POSITIVE FROM NEGATIVE.—I thank you very much if you will tell me if there are any means of making a negative into a positive, "without contact printing or using a camera," by treating it chemically.—SIMPLEX.

If the negative is a thin and somewhat under-exposed one with quite clear shadows, an easy means of producing a positive from it is to bleach it in mercury bichloride solution, wash thoroughly, and apply a *very* weak (about 1 grain per oz.) solution of sodium sulphite for a few moments. Thus treated, the negative has the appearance of a positive when viewed from the glass side. It is dried and backed up with black velvet from the film side.

FOGGED NEGATIVES.—I have been taking a few curious things in India on my tour in this country with my master, and generally the work is outdoors. I always take two plates of each subject, and invariably I find plates with these kinds of marking on them; one plate is unaffected, while the other is. Sometimes both are affected, and sometimes both are good. Please inform me the cause and remedy, if any. Climate has nothing to do with it. Even in cold climates I had markings. Two plates developed in same developer, one had marking, other none. Pyro soda at 90 deg.

There are two reasons why we cannot help:—(1) The negatives —packed between cardboard only—arrived in a thousand pieces; and (2) you give us no clue to your method of working, or the materials you use. We would assist you if we could.

LANTERN LENS.—1. I have the usual lantern for projection, but would like to make the distance between the lantern and screen much less and keep the picture still the large size. Can you inform me how I may do so?—MOVR.

1. You need a lens of shorter focus. If you said what focus your present lens has we could advise you, but you can judge for yourself by referring to the table of lantern distances in the "Almanac." 2. We cannot trace the receipt of a query on the printing of P.O.P. by artificial light. An enclosed arc lamp is the best means, the prints requiring from five to fifteen minutes. If you use a weaker light, say incandescent gas, you must develop, and the process is not very satisfactory.

WASHER.—Apparently the stains are due to imperfect fixing and washing. As you have not mentioned the paper used, the method of toning, or given any data whatever, we cannot answer you further.

REWOG.—The process is a trade secret. We do not know it.

RENOVATING FRENCH POLISH.—My cameras, mahogany, and stand have become very dull through the French polish having lost its brightness. Is there anything I can apply to brighten it up a bit, as I cannot afford just now to send the things to the makers to be repolished?—MARCUS.

There are many French polish "revivers" on the market, and they may be had at any of the oil shops. The following is a recipe: Linseed oil, half a pint; spirit of camphor, 1oz.; vinegar, 2oz.; butter of antimony (tri-chloride of antimony), ½oz.; ammonia, ½oz. Although this is a very old recipe, it is a very good one, as we know from having used it. Before the reviver is used the work should be thoroughly cleaned by washing it with soap and water.

BREAKING AN AGREEMENT.—Three years ago I entered the service of — and Co., on a three years' agreement, at a progressive salary. They have now served me with a notice to leave at the end of the first year—the first of next month. The reason, they say, is that business is too bad to keep me on.—OPERATOR.

If the agreement is rightly framed and properly stamped, you cannot be compelled to leave. The falling-off of business is not a valid reason for breaking a properly-made agreement. If you are really discharged before the termination of the agreement, you will have good cause for action for damages for wrongful dismissal.

LENS QUERY.—I recently bought, for 15s., at a pawnbroker's, a lens by Dallmeyer, marked "Actinic Triplet." The front lens is smaller than the back, and there is a still smaller lens in the

centre of the tube. The back lens is somewhere about 3in. in diameter. I bought the lens because Dallmeyer's name is on it, and I concluded that it was good for some purposes. I shall be indebted if you will be good enough to inform me what they are and what size plate it will cover?—J. K. SIMPSON.

The triplet is an old form of lens introduced many years ago for similar purposes to the rectilinear lens, which has quite superseded it now. It is slower in action than the RR, but still it produces good work. As the focus of the instrument is not stated, we can give no idea as to what size plate it will cover. On reference to an old price-list, however, we see that a lens with a back diameter of 3½in. will, with the full aperture, cover 10x8, and when stopped down 15x12. When the centre combination, which is a negative, is removed, it can be used for portraits of the half-plate size, and is then nearly as rapid as an ordinary portrait lens.

**DAMAGED GLASS POSITIVE.**—We have an old collodion positive brought to us to copy, and restore if possible. The picture itself seems all right, but is covered with minute cracks or fissures, which do not seem to show so much when looked at in some lights as in others. Can you kindly tell us the best way of dealing with it, as it belongs to a good customer, and if we can get a satisfactory copy it may possibly lead to an order for an enlargement at a pretty good price. Awaiting the favour of reply in an early issue.—J. and Co.

Without seeing the picture we cannot advise definitely. However, in all probability it is the black varnish on the back of the plate that has cracked. If that is the case the matter is simple. Scrape it off the glass and apply fresh, and the picture will be as good as at first. Sometimes, however, the black varnish was applied on the front of the picture, in which case we fear little can be done, as, probably, the collodion film, as well as the varnish, has cracked. Sometimes another coat of black varnish will improve matters, but this treatment is more or less risky. Supposing the varnish is on the face, the best thing to do is to place a piece of black velvet on the picture and then copy it from the glass side. Often, when this is done, the cracks are not very apparent in the copy.

**REVERSED PICTURE.**—I sent a portrait negative to one of the advertisers in your paper to have a 20 x 16 bromide enlargement made from it. When I received it I was surprised to see that the portrait was reversed. What should be the right side was the left. I returned it with the request that another should be done to replace it. I received a reply that mistake had been made, but as the enlargement was a portrait it did not matter, and at the price they did their work it would mean a loss to them to make another. They, however, said they would do another at half-price. Ought the people to make any charge through their mistake?—R. S.

This is a simple thing on which we should have thought any photographer would not require advice. You should refuse to accept the picture and pay for it, and demand the negative back.

**DAMAGED MIRROR.**—I have entered into an arrangement with an engineering firm here to take photographs of the machines they make for their catalogues, but the negatives must be reversed, as regards right and left. I purchased a reversing mirror and obtained satisfactory pictures with it. In time it became tarnished and I attempted to polish it, according to the directions given. But directly I rubbed it with the polishing pad the whole of the silver came off the glass. I have sent it now to be resilvered, and shall be glad if you can tell me how the mirror can, when necessary, be repolished without this trouble, as I am told they can be repolished many times?—C. WADE.

It is clear that the silver surface was damp when the polishing was attempted. When in that state the silver film is but slightly adherent to the glass, though it is firmly so when quite dry. In future, before beginning to polish the mirror place it at some distance in front of the fire, for a time, so that all moisture is driven off and the glass is made quite warm. Then it may be polished without fear of damage. When out of use mirrors should be protected from the air; they will then retain their brightness for a long time. They should always be stored in a dry and warm place.

**RIGHT TO PHOTOGRAPH.**—I shall be very grateful for your opinion on the following little matter: Last week I set my camera up on the road before a very pretty old house. Just as I had exposed the plate a gentleman came running out and asked what I was photographing his house for. I told him it was for postcards which I was publishing. He asked me for my name and address which I gave him, thinking I might get an order from him. I then got into a passion at what he called my impudence in photographing his place. He then told me that if I dared to publish the pictures he would at once place the matter in the hands of his solicitors, and adding that to prevent "this sort of nuisance" some time ago he had the house photographed and made the picture copyright, so that any other pictures of it would be infringements of it. An early reply will oblige.—J. KEBOURN.

Evidently the gentleman is under a misconception as to his supposed rights, or he is trying to bluff you, possibly the latter. The making of a photograph of the house copyright does not make the house itself copyright. Anyone is free to photograph the latter and do what he likes with the pictures. You cannot be restrained from publishing your photographs, however your property may be threatened.

**MAKING CARBON TISSUE.**—I wish to make some carbon tissue my own use, as I cannot get the particular colour I want by purchase. I shall be glad if you will inform me if the formula given in Wall's book on the carbon process is the same as that employed by the best makers of the tissues now on the market. If not, you give me it?—T. A. WALTHES.

This is a query we cannot answer, as we are not in the secret of the various commercial tissue manufacturers. The formulae given in the book are typical of those that have been published, and it may fairly be assumed that they will answer. Of course, commercial firms do not publish what they have gained by years of experience and research, they naturally keep that to themselves. We should say that you would find it far better to buy the tissue than attempt to make it yourself in small quantity, and you will be hard indeed to please if, amongst the scores of colours and tints now on the market, you cannot find one to suit you.

**CARBON PICTURES ON JAPANESE PAPER.**—In the "B.J." of January there is an article on producing carbon prints direct on Japanese paper without its being wetted. I am anxious to make such pictures and I have tried, but with very little success and with a waste of this expensive paper. But I should say at once that I have not followed the instructions you gave in their entirety because I have used the ordinary flexible support instead of indiarubber support you mentioned. I find that in applying gelatine to the picture that the light tones wipe off. Is there any way of avoiding that, as I do not want the trouble of making rubber support?—A. F. WILKINS.

In the article it was specially mentioned that the trouble referred to would generally arise if the usual flexible support were employed and we do not know of any way of avoiding it. The preparation of the rubber support involves but little trouble, and with this there is no difficulty whatever. We expect that if you desire to produce these pictures with certainty you will have to employ rubber-coated paper as the temporary support.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are taken absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

**Bromoil Exhibition.**—The present exhibition of bromoil prints at the house of the "British Journal" will close on Wednesday May 27. It will be re-opened on Monday, June 1, at the "adevous" of Messrs. John J. Griffin and Sons, Ltd., Kings- where the pictures can be seen until June 20.

**Modern Studio.**—Mr. Drinkwater Butt's articles on this subject, mentioned in our issue of March 27, conclude on p. 395-6.

**Our leader** this week contains some useful hints with regard to repair of broken negatives. (P. 391.)

**Our commerce** some articles by David J. Howell on Canada as a for photographers on p. 393.

**An important improvement** in the ozobrome process worked out by Mr. Manly is described on p. 392.

**The use of the camera for making business photographic records** the use of contractors and manufacturers is dealt with in an article commencing on p. 396.

**An important paper on the colour-filter and the isochromatic plate** in stereo-graphic photography, by Mr. R. J. Wallace, commences on p. 398.

**An article on the sizes of stereoscopic prints**, by L. Stockhammer, appears on p. 400. We comment upon it on p. 390.

**Photographic Chemistry.**—The syllabus of Dr. Scott's lectures at Royal Institution will be found on p. 406.

**Another free photograph case** is reported in our "Commercial Legal Intelligence." (P. 406.)

**A new retouching medium** is described by a correspondent on p. 407.

## EX CATHEDRA.

### The Photographic Convention.

By the time these lines appear the full programme of the Brussels meeting of the Photographic Convention will have been published. Its pages show the completeness of the arrangements for the convenience of Conventioners, and the excellence and variety of the excursion and literary fixtures. We are glad to learn that the applications for membership up to the present constitute a record among recent meetings, and that without a doubt the Brussels meeting is assured of a success which will be a fitting appreciation of the hospitality of the Association Belge, to whose initiative the selection of the Belgian capital as a meeting-place is due. Sir Cecil Hertslet has himself taken a great interest in the arrangements, and, with Captain Van Berger and M. Van der Kindere, has done a great deal in the preparation of the week's programme.

\* \* \*

### The Colour Exhibition.

In transferring its annual exhibition from autumn to summer, the Society of Colour Photographers has no doubt done well. It has certainly shown its courage in holding its second exhibition within six months of the first, but the support both of its members and of other colour workers turns out to have justified this course of action. The exhibition of last September-October brought together a representative collection of screen-plate colour transparencies, among the earliest to be seen in this country. The forthcoming show will amount to a demonstration of the later and more perfect results by the Autochrome process, and will in addition show the continued progress in three-colour work on paper. In response to many requests, the exhibition will remain open every evening of the week until 8 p.m., a convenience to the public which has been made financially possible by charging the sum of sixpence for admission to the exhibition.

### On Scrapping Pictures.

According to a newspaper report, M. Claude Monet has created a sensation by destroying a number of his own paintings that he did not consider worthy. It is stated that the pictures represented 'three years' labour and a probable market value of £20,000. Whatever the value of the pictures, the occurrence is an instructive one. It is by no means unusual for a painter who has some respect for his work to destroy the result of, perhaps, many months' work, because he does not think it good enough, and because he cannot see any way of improving it. The total amount of what ordinary persons would probably regard as fine works of art annually destroyed by painters would probably astonish the general public if they could only get some idea of it, but it is greatly to be feared

that the destruction of a finished photograph is a thing that seldom happens, however bad it may be. The manner in which a photographer will cling to a piece of rank rubbish in the way of a photograph is painful at times. His only excuse is often that he cannot secure another negative of the subject, and the idea that a bad picture is worse than none at all never seems to occur to him. Many photographers could by stringent weeding out of their bad results produce a small collection of really good work that would enhance their reputation and be worth seeing. By keeping the bad samples they simply lower the value of the whole collection, and lose credit. The example of M. Monet may convert some of them, but we fear the movement will not spread as far as it might, for, after all, it is mainly a matter of training. An artist is trained to look upon bad work as more or less criminal, or at least immoral; therefore he has little compunction in destroying it.

\* \* \*

#### Effects of Monocular Relief.

Prof. Gustave Michaud, in the "Scientific American," has recently drawn attention to some effects of monocular relief that he seems to think demand a new explanation. Taking a simple geometrical figure, such as a circle, he draws upon it lines in various directions, and considers that by so doing he has introduced a certain amount of what he calls artificial distortion that gives an appearance of relief to the whole diagram when it is viewed with one eye or through a pinhole. The explanation is, however, much more matter-of-fact. All that he really does is to introduce lines that give a more or less accurate effect of perspective, and it is fairly well known that a drawing in perspective of a simple object, especially when correctly shaded, will show very obvious relief when viewed monocularly from the right view-point. The effects that he obtains are due to nothing more than a style of drawing that more or less simulates a true perspective effect, and in some cases he appears to aid the effect by a rough attempt at shading. Suppose we represent a sphere by a circle. This will show no effect of relief; but if we add to it lines representing meridians a spherical effect is imparted at once, even if the meridians are not quite correctly drawn. On one of his diagrams he has drawn curves that resemble two sets of great circles at right angles to one another, and the crowding of these circles near the margins has introduced an appearance of shading, the result of all which is that an effect of a hemisphere is obtained when we view the drawing with one eye from a certain distance. Sometimes he uses a pinhole to assist the illusion, but this only aids when the right viewing-point is very near the paper, as it is in some of his examples. This is the true explanation of the action of the pinhole, though he has evolved a different theory that we cannot quite follow, and of which we cannot obtain any experimental confirmation.

\* \* \*

#### The Size of Stereoscopic Prints.

On another page we publish an article by M. L. Stockhammer, in which the advantages of short-focus lenses and small wide-angle views are fully set forth. There are, however, one or two points raised in the article that require further consideration. The objection to long-focus lenses is that the large images produced overlap one another to such an extent that a very small field of view is left. It is stated that the more the lenses are separated the less do the two fields overlap, and the greater is the width of image permissible; but, in saying this, the author seems to have forgotten some important points. Unless an extra long plate is used the amount of image saved in the centre of the plate is lost again at the ends, so that little or

nothing is gained. As a matter of fact, if the subject near object, more of the image is lost, because mounting the prints they must be placed nearer other than if less widely separated lenses had been used. Then, again, the writer states that the width of the images is limited by the separation of the eyes, but with prismatic stereoscope this is an unnecessary limitation. Prisms permit the use of wider prints as a wider mounting separation is required. As we have before explained the proper separation to be observed between corresponding distant points is the separation of the eyes added to the width of one prism, which amounts to nearly the same with most people when  $\frac{3}{4}$  in. prisms are used. How these discrepancies in the author's arguments more or less balance each other, and the objections he has to his apparatus with long-focus lenses are only too well known in fact. We do not, however, think that his remedy is altogether the best one possible. It is, no doubt, the best for the single-plate cameras and the "Brewster" type of stereoscopes in ordinary use, but such types of apparatus are by no means the most desirable ones that could be adopted. By the use of reflectors both cameras and stereoscopes could be modified so as to render large images serviceable, and it is on these lines that we should be inclined to look for improvements. The Wheatstone stereoscope was a far superior instrument to the refracting stereoscope that Brewster claimed so much for, and can be seen from the article in our issue of April 22. The Dixie method of stereoscopy, both cameras and stereoscopes can be revised in such a manner as to render the use of large views quite feasible. So long as we keep the present type of apparatus M. Stockhammer's arguments in favour of short-focus lenses will hold good, but there is no specially valid reason that we know of for keeping to this type at all.

\* \* \*

#### The Packing of Negatives.

Breakages due to the careless packing of negatives are pretty frequent, and just recently we have received complaints to the effect that retouchers are very prone to be careless in this respect. A correspondent complains that retouchers who advertise for work return negatives, which have been entrusted to them to see what they can do, simply wrapped up in a piece of paper, so that they are their owners smashed into fragments. Our correspondent remarks that in such cases they do not get any work, and this is the very point, one would think, the culprits themselves should have thought of in the beginning. There is no excuse for such carelessness, for it is a perfectly simple matter to pack a negative so that it will pass through the post safely. An ordinary sound plate-box well stuffed with soft paper, and stiffened with a few pieces of boards that photographers always have handy, will be found to be if the whole is well wrapped in corrugated packing. A wood box is not a difficult thing to find, or even a very expensive thing to purchase, if the safety of a valuable negative is in question. In cases such as the ones quoted by our correspondent, the owner can and should take the precaution of sending his negatives to the retoucher in a safe box that can be used for their return. If he insists that the negative is to be returned in the same package then the retoucher will be left without any excuse for the loss. It is, however, only fair to add that this is a case of carelessness is not confined to retouchers by any means. We ourselves have had considerable trouble with our photographic secretaries. We have sent them valuable negatives packed in special wood boxes, but we have seldom seen those boxes back again. Generally the negatives have re-appeared in cardboard and brown paper packings, in spite of the precautions we observed

ending them away. This kind of thing renders one reluctant to run risks, and it is distinctly unwise policy on the part of those responsible.

## BROKEN NEGATIVES AND THEIR REPAIR.

NEGATIVES, as everyone knows to his cost, occasionally get broken in the printing frame, and often in other ways. When one breaks in the frame the reason, usually, is that the rebate of the latter is uneven, for the glass at present used for dry plates is rarely sufficiently unequal to cause a defect. If, as is more likely, the frame is the cause of the fracture, it should at once be discarded or broken, so as to avoid future trouble. However, it generally happens, owing to the "cussedness of things," that when a negative gets accidentally broken it is a valuable one, commercially, or one that cannot be retaken. In such an event it is worth going to considerable trouble to effect repair, and the process, after all, is not so difficult a matter as some seem to imagine it.

We will, therefore, give instructions as to the way by which even badly broken negatives may be made at least serviceable, and, to professionals, often still profitable in the way of future orders. In some instances the negative may be made in every way quite as perfect as if it had not been broken at all. If, for example, a negative gets cracked in the printing frame, it is more than probable that the gelatine film is not broken through. In this case the matter is a very simple one to deal with, as the uninjured part can be removed from the broken glass intact and be put on to another plate, when it will be quite as good as the original.

In this case the first thing to do is to place the negative carefully so as to avoid breaking the film—lay it upward on another plate a size or two larger. The next thing is to harden the film with formalin or chrome to prevent its expansion when removed. This is best done by putting the two plates in 10 per cent. formalin for ten minutes or a quarter of an hour; but before doing that it is well to cut through the film an eighth of an inch from the edges of the plate with a penknife. After treatment with the formalin the plate is slightly rinsed under the tap and immersed in a dish of water to which a few drops, per ounce, of hydrofluoric acid has been added. This, it should be mentioned, must be contained in an ebonite or celluloid tray and not in porcelain or glass. After a few minutes the film will be seen to be leaving the glass at the edges, and then by gently rocking the tray backward and forward the film may be floated off, and the pieces of broken glass and the other plate removed. The acid water is then drained off and the tray filled with clean water once or twice, to remove any fluoric acid. A clean glass plate is then slid into the water and the film floated in position upon it—avoiding air bubbles—and the water then slowly and evenly withdrawn in contact, the film being held to the glass at the upper corners between the thumb and fingers. It will be well to have at hand a small camel-hair brush to smooth down the film if necessary, but that is rarely required if the manipulations are neatly performed.

The plate, with the attached film, is then reared up to drain, and dry spontaneously. In some cases the film when dry will adhere firmly to the glass, if that be perfectly clean and the film has not been unduly hardened; but that cannot be relied upon, therefore it is better that the new glass be always coated with an adhesive. The best for our present purpose is a solution of gelatine—say one ounce in a pint of water. The plate is floated over with a thin coating of this, which is allowed to set firmly, and then the film is floated on that instead of the original glass.

the bare glass there will be no risk of its splitting off at any future time. Should the film, through insufficient hardening, expand during the stripping, it can be brought back to its original dimensions by immersing it in a dish of methylated spirit.

There is an alternative method of removing the film from the glass which some may prefer to the one just described. It is to soak the plate in a weak solution of washing soda for five or ten minutes, or until the film is thoroughly permeated; then slightly rinse and put into dilute hydrochloric acid. In this way carbonic acid gas is evolved between the glass and film, and the latter becomes liberated. On the whole, however, we ourselves prefer the fluoric acid method. Another method of removing the film is described on page 808 of the "Almanac" for the current year, and is particularly easy in execution.

In the foregoing it has been assumed that the negative has been cracked only into two pieces, and that the gelatine film has not been broken through. But it may happen that the damage has been more serious, and that the glass has been broken into several pieces. In such a case as this it will be obvious that it is impossible to properly join the pieces of film after they are detached from the glass, particularly if they have expanded in any way. Therefore they must be placed and secured in position before removal from the plate. The pieces of negative should be neatly arranged in position on a glass plate larger than the negative, say a whole-plate for a half-plate negative, and secured with narrow strips of gum-paper. It goes without saying that they must be very accurately joined. A good way of doing that is to press the edges of the fractured plate against a straight edge, say the side of another plate, for if the edges are perfectly true the other portions will be true also. If the negative is in many portions it is a good plan to secure, with gum paper, two strips of glass at exact right angles to each other on the large plate, into the corner of which the pieces can be pressed while being secured. The exact right-angle can easily be secured by putting a half-plate on the larger one, and then cementing the strips against two sides of it. When the whole of the pieces of the broken negative are got into place, and are firmly secured, the edges of the fractures should be closely examined, and if any little points of the film seem detached from the glass they should be touched on the under side with gum and pressed in contact with it, so that they will not become separated later on.

We will now assume that the negative is neatly joined and firmly fixed to the large glass. This is now placed on a levelling stand, or is otherwise levelled, say by wedges of wood, and some very thick enamelling collodion poured on, so that it is an eighth or three-sixteenths of an inch thick. The whole is then allowed to rest, undisturbed, till the collodion has thoroughly set and become firm, though not dry. This will take an hour or two, or more, according to the temperature. Next the film is cut right through to the glass, round the edges, with a sharp knife. The plate is now put into water and hydrofluoric acid, as described above, and kept rocking so as to facilitate the removal of the collodion solvents that may be remaining. In a short time the edges of the film will begin to show signs of loosening from the glass, but it is well not to hurry the separation, or some small piece of the gelatine film may possibly become detached at the edges of the fractures. When the film has come off we have the pieces of negative securely held by the collodion. The film should then be lifted out and put into a dish of clean cold water. If a good body collodion has been used and applied thickly as directed, it can now be freely handled, of course with some care. If not it must be lifted out on

another plate. After rinsing, the film is ready for attaching to another glass, and that is done in the same manner as described above. It may be as well to mention here that the gelatine-coated plate, when immersed in the water for the transfer, may carry with it some minute airbells. These should be carefully removed with a flat camel-hair brush before the lifted film is brought in contact with it, as they cannot afterwards be easily got rid of.

It will be noticed that nothing has been said in this case as to hardening the negative film before stripping. In this case this is not necessary, as the collodion film, which is unaffected by water, holds it so firmly that no expansion takes place. If the negative was only broken into two or three pieces, and the work is neatly carried out, the fractures will scarcely show at all. If, however, they do, they must be touched out with pencil or brush.

## THE COMMERCIALISATION OF OZOBROME.

In a circular of instructions just issued by the Ozobrome Company the announcement is made of important improvements in the Ozobrome process, the sum and substance of which should be of the greatest interest to workers of the process, and particularly to those who employ it for commercial purposes. The Ozobrome Company have in their literature laid considerable stress upon the natural advantages afforded by their process for the commercial production of carbon prints and enlargements, particularly the latter, and their materials have, no doubt, been subjected to considerable experiment by professional photographers and the many firms who undertake enlarging and printing work for owners of studios. Simple and speedy as the ozobrome process is, there has in the past been one feature which, from the professional point of view, was a drawback to its constant practice. This lay in the necessity of renewing the pigmenting solution when producing a large number of pictures of perfectly uniform character. It was found that while the first three, four, or five ozobrome prints treated in a pigmenting bath were perfectly uniform, the quality was liable to fall off to some slight extent in the case of later prints passed through the same pigmenting bath. The necessity of having to renew the bath, apart from the question of cost, was an obvious inconvenience to the worker undertaking the process on a considerable scale, and it is therefore of considerable interest to find that Mr. Manly has worked out a modified procedure which disposes of this drawback. The new working method entails only the slightest modification of the present procedure, and costs practically nothing more than at present. It consists in using a weak bath of hydrochloric acid instead of water for the preliminary soaking of the pigment tissue. The latter is then transferred direct into the pigmenting solution (one part of stock solution to four of water), and the subsequent process, including contact with the bromide print, conducted as before. Apart from the regularity which this modification, when worked according to a system, gives to the process, it also allows of the method being adapted to originals of different characters, so that the ozobrome result from a weak or from a hard bromide print can be corrected to a considerable extent. The difference in result is due to the absorption by the gelatine of the tissue of a definite quantity of acid solution. The following working instructions are taken from the new circular just issued by the Ozobrome Company. The method, it should be observed, has involved a modification of the pigmenting ozobrome solution, and all solutions applicable to the new procedure are numbered 701 and upwards. Those with a lower number should be worked according to the old instructions—that is, using a preliminary water-bath for the soaking of the tissue.

### Acid Bath.

Pure hydrochloric acid...	1 drachm. ....	5 cc.
Water .....	25 oz. ....	1,000 cc.

This is a half-per-cent. solution, and it should be made up exact measurements, as the proportions are important. The pigment plaster is placed, face upwards, in this solution, and is kept beneath the surface during immersion, a mop camel-hair brush being suitable for this purpose. As a guide to the time of immersion the following table may be taken:—

	Immersion of plaster.	
	Seconds in acid bath.	Seconds, pigment bath.
For a normal bromide print with a good range of tone .....	30	90
For a bromide print that is weak and grey .....	10 to 20	90
For a bromide print that has strong black shadows and harsh contrasts	40 to 60	90

On removing the plaster (tissue) from this acid bath it is allowed to drain thoroughly, and is then transferred, face upwards, to the pigmenting solution, where it remains for the time of one and a half minutes. It is then removed, allowed to drain, and drawn, face downwards, twice across the surface of a bath of clean water. The bromide print lies face upwards, and the sheet of tissue is brought, film downwards, in contact with it so as to avoid air-bells. The two sheets are then removed from the water together, squeezed, left in contact the necessary time, and the remainder of the process is then proceeded with in the well-known manner, either of Method 1 or 2, of the ozobrome process. The first, it will be remembered, gives a pigment print above the bromide image, whilst the second gives a pure pigment print by transference to single transfer paper.

To test this modified ozobrome process, we selected a bromide print showing plenty of fine gradations in the high-lights, and the result was a very marked success. The process worked without a hitch from start to finish, and all the gradations were beautifully preserved. We employed the second, or transference method, and treated the bromide print as a normal one, giving thirty seconds in the acid bath and ninety in the ozobrome bath. We have not yet had time to test very thoroughly the keeping qualities of the modified ozobrome solution, but it is evident already that they are far superior to those of the bath used in the original process. Mr. Manly is to be congratulated on what is certainly a very important improvement in this most useful process.

**PHOTOGRAPHING SUSSEX.**—Mr. J. C. Stenning, of Bexley, Saffrons Road, Eastbourne, has undertaken the Local Secretaryship of the Photographic Record and Survey of Sussex Association, and will be glad to give all information and assistance to those who may be willing to help in the work of obtaining photographic records of Sussex.

**MR. ERNEST WILLIAMS**, who has filled the position of manager of the photographic department of Messrs. Spiers and Pond for the last four years, has transferred his services to Messrs. A. Gamage, Ltd., of Holborn. His early training in chemistry and long experience in the photographic trade will doubtless ensure him success.

## CANADA AS A FIELD FOR PHOTOGRAPHERS.

[We are so often asked about the present conditions in Canada as they require to be known by a photographer with thoughts of going to that country, that we may direct special attention to the following article, written at our request by a Canadian reader of the "B.J." familiar both with the country as a whole and with the photographic business.—  
— "B.J."]

A great deal has been said and written of the vast extent of the Dominion of Canada. As the literature issued by its Government and railways goes into this fully, it will not be necessary to describe it. One or two facts, however, should be kept in mind. Canada is a land of great distances. It takes about a week to traverse it by express train, and it is almost as great a variety of climate as Europe. To give an idea of its resources and possibilities, it will be best to divide the country in sections.

The Maritime Provinces, Nova Scotia, Prince Edward Island, New Brunswick, have not attracted as much attention from newcomers as have the provinces to the west, yet they have made steady progress. In addition to their fisheries, lumbering, shipping, the growth of iron and steel industries, and the development of coal fields, are perhaps the more recent outstanding features of their progress. Some parts are attracting an increasing number of summer tourists, notably the Annapolis valley in Nova Scotia, the most famous apple orchard country in Canada, and known to tourists as "the land of Evangeline." Nova Scotia, the principal city is Halifax, the capital, with a population of 40,000. It is a seaport, open all the year, and a winter port for the Canadian mail steamers. It is a thorough English city, and regarded by western Canadians as being somewhat sleepy. Sydney, where the great steel and coal industries are centred, has a population of 9,000.

In New Brunswick, St. John (40,000 population) is the largest city, being the winter port of the steamers of the Canadian Pacific Railway, and where they have built extensive docks. The city has every prospect of substantial growth. Fredericton, the capital, with a population of 7,000, and Moncton (9,000) are the other important places.

The province of Quebec, being almost wholly occupied by French-speaking people, who are perhaps less aggressive than English of the other provinces, offers very few attractions as a place of settlement for the Anglo-Saxon from over the States. Quebec, the capital of the province, is considered the most picturesque and quaint city in America. It attracts a great number of tourists, who sometimes come in such numbers to exceed the large hotel accommodation. It is the summer resort of several trans-Atlantic lines of steamships, and has recently experienced a revival of business and growth. Less than a quarter of its population of 70,000 are English-speaking people.

Montreal, some 200 miles further up the river St. Lawrence, is the metropolis of Canada. It has a population of nearly 1,000,000, of which about two-thirds are French. Though a university city, with many English and French colleges, it has more and larger manufacturing industries, and a greater amount of shipping, than any city in Canada. The head offices of the two great railway systems are situated here, and each contains a fully equipped photographic department. Some of the large manufacturing plants employ a photographer for their work exclusively.

### Central and Western Canada.

It is in the central and western parts of Canada, however, that the greatest progress and development is taking place, and to these provinces the greatest attention is attracted. The western part of Ontario has been well settled for many years, the majority of farms have substantial buildings and richly cultivated fields. Many of these homesteads have been in the possession of their owners for several generations. The

cities and towns are of considerable size, and in many there are manufactories of various kinds, whose products are sent all over the Dominion, or exported.

Ontario at present is the chief manufacturing province; its capital, Toronto, is a city of 300,000 population, almost wholly English-speaking. It has a large university and many colleges, there being 5,000 students in attendance. There are many and extensive manufactories. The latest directory of the city showed sixty-three photographic establishments. Most of these are one-man studios, the proprietor doing all the operating, and employing one or more assistants.

The other principal cities are:—London, population 35,000; Hamilton, 55,000; Ottawa, the capital of the Dominion, population 70,000, partly French; and Kingston, 25,000, the conditions being somewhat like Toronto on a smaller scale. Hamilton, perhaps, has more industrial concerns than the others.

The northern and western part of the province, usually termed New Ontario, is largely undeveloped. Great interest at present centres in the extensive and valuable minerals recently discovered. Cobalt silver ore of marvellous richness has attracted the world's attention. This region is about eleven hours' railway journey from Toronto. Already the more adventurous photographer has been "cleaning up" good money there. North of this, large areas of good farming land are being opened up by the building of railways. To the west of this territory is a wild and rough country, much of it mineral-bearing, and largely forest-covered. All this north country has long, rigorous winters, but bright, warm summers that attract great numbers of people from older Ontario and the United States.

At the head of the great lakes are the twin cities of Port Arthur and Fort William. They will eventually form a large city, for all the lake traffic to and from the Great West begins and ends here. It has large terminal facilities for three railways, among these being some of the largest grain elevators in the world. At present the photographic possibilities have been largely discounted, and competition is keen. Back of these cities, and to the west, large lumbering and mining operations are being carried on; Kenora, a thriving place, being their centre, and the most western town of prominence in Ontario.

### The Wheat-Growing Districts.

Manitoba is the first of the prairie provinces, and the beginning of the great wheat-growing lands that stretch through to the Rocky Mountains. Its capital, Winnipeg, is the first city of Western Canada, the growth and progress of which has been so rapid, and yet substantial, as to be nothing short of marvellous. Its citizens are very much impressed with the achievement, and no comparison or eulogy, however flattering, is received by them with other than the utmost complacency. There is a great amount of business done; every year sees an increasing number of manufacturing industries established. The city has many nationalities among its inhabitants, but the English-speaking races are very largely in the majority. Its population has nearly trebled in the last five years, and is now somewhere about 125,000. There were about twenty photographic studios in the city in 1907. The province of Manitoba is fairly well settled, and many thriving towns are located on its extensive network of railways, Portage la Prairie (5,000) and Brandon (11,000) being the most important.

Two new provinces (Saskatchewan and Alberta) lie between

Manitoba and the Rocky Mountains. The first in the westward journey is Saskatchewan, with an area of nearly 230,000 square miles, being 700 miles from south to north, and over 400 from east to west. Wheat-growing, ranching, mixed farming, and lumbering in the north, are the special industries of the province. The principal towns are Regina (7,000), the capital; Moose Jaw (7,000), Prince Albert (4,000), and Saskatoon (2,500). There are a number of lines of railway under construction, and new towns are springing up continually. Alberta has even greater area than its sister province, containing over 280,000

square miles. It has perhaps the greatest possibilities of any of the western provinces, having a great variety of natural resources. In addition to wheat-growing, cattle-raising, mixed farming, and great lumbering possibilities, it has rich mineral deposits, coal, gold, silver, and other minerals; oil and gas have been found in many districts. It has some good-sized towns, the most important being Calgary (15,000), Edmonton (12,000), Strathcona (3,500), and Medicine Hat (3,500).

DAVID J. HOWELL.

(To be continued.)

## OZOBROME AS A METHOD OF INTENSIFYING NEGATIVES.

A NEGATIVE that requires neither intensification, reduction, nor retouching is the desire of every photographer. But how seldom one gets it. It need not be said, however, that these after-processes detract from the value of the picture. Nay, they oftentimes enhance it.

When intensification has had to be resorted to it has been customary to use solutions of which mercuric chloride or uranium formed the basis. But to these can now be added another. It may not be new, but, so far as I know, it has not hitherto been published. The story of its discovery (if it is one) may best be told in a personal way.

In the beginning of November I cycled out to a haunt of mine for the purpose of securing a picture of a few scattered trees against a sunset. In this quest I was successful. The sky was beautiful when the photograph was taken, but the after-glow of sunset was a "poet's dream." My way homewards lay along the banks of a river, and, as I had several unexposed plates, I dismounted at various points on the roadway and prospected on the river bank with the view of finding a suitable composition in which to include the magnificent aerial display. It was not until home was nearly reached, however, that a suitable one was found, and by that time passing vehicles had their lamps alight. Reds were predominant, and a long exposure on a rapid isochromatic plate with screen was necessary to get even a trace of colour values. As little movement was taking place, two minutes' exposure, with an Aldis anastigmat working at  $f/6$ , was allowed. It was far too short, and when the plate came to be developed with a normal pyro-soda solution, it was 15 minutes ere the faintest image appeared. The plate was then washed and placed in a stand development tank filled with rodinal, 1 in 75. Here it was left for two hours. It was then examined, and, though the picture was there, and some representation of the cloud effects, it was a mere ghost of a negative. After rinsing, fixing, washing, and drying, it was placed among

the "wasters," with the regret that so much time had been devoted to it.

### Intensifying a Ghost Negative.

Some time afterwards, when working ozobrome, the thought struck me that it might be possible to impart some life into this ghost by the process. A sheet of sepia tissue was selected. It was sensitised in the ozobrome solution and under water was brought into contact with the negative. Having squeezed them into closer fellowship, they were left in juxtaposition for ten minutes. At the expiry of that period they were plunged into a dish containing luke-warm water; and when the backing paper was released, development was carried out by gently laving with a teaspoon. In a short time the negative was free from all superfluous colour, and the faintest trace of an image was left. When it was re-developed with amidol, however, a great transformation took place, and a negative of printing density was procured. It did not come up to exhibition standard—far from it—but it allowed one to illustrate, in a faltering way, it is true, the prevalent atmospheric conditions. It also demonstrated clearly the fact that ozobrome could be successfully used for intensification.

Some of the pigments may be quite unsuitable for this purpose, and the various shades will not give the same result. But the latter fact may be a strong point in its favour. Different degrees of under-exposure or insufficient development could be treated with different colours—viz., an extreme case of under-exposure by a dark pigment, and a slight case by one of a lighter hue.

The introduction of ozobrome has put a valuable implement in the hands of photographers, and the knowledge that it can be used in the way indicated may save many a picture where an error in exposure would have otherwise militated against its successful reproduction.

WILLIAM FINDLAY.

SHOPS AND THE LONDON BUILDING ACT.—The London County Council on May 12 discussed the Building Acts (Amendment) Act, 1906, in its relation to shopkeepers. The matter arose on a suggestion by Capt. Fitzroy Hemphill that the Act was not being adequately enforced in regard to the provision of means of escape from fire. Thirty-four lives had been lost since 1896 which would have been saved if the Act had been enforced. Mr. Howell Williams, however, took the view that if many of the provisions of the Act were applied it would press most harshly on small traders. There was scarcely a building in London which complied with all the technicalities of the Act, and its principal object seemed to be to provide officials with a means of wringing fees from traders and ratepayers. Mr. Edward Smith, M.P., called attention to the danger from fire caused by the custom in London of building single storey shops in front of houses several storeys high, and suggested that such shops ought to be provided with fireproof roofs. Mr. F. Goldsmith, Chair-

man of the Building Act Committee, promised not to apply the Act in too strict a fashion whilst making full use of it to abolish death traps.

A CORRECTION.—In reference to the notice of Mr. Swaine's new studio in Bond Street, which appeared in our issue of last week, we would wish to correct one statement in reference to the time with which Mr. Swaine was with Messrs. Lafayette. Mr. Swaine was with Messrs. Lafayette for a period of twelve months.

### CONVENTION LYRICS. No. 3.

Writes that charming young lady of Ghent  
(To know her, oh! how I long),

"Your poetry's great

But allow me to state

Your French is most horribly wrong."

But how does one pronounce G-H-E-N-T?

# THE MODERN NOTE IN THE DESIGN AND FITTING OF PHOTOGRAPHIC PREMISES.

[This article concludes the series by Mr. Drinkwater Butt that began in our issue of March 27.—Eds. "B.J."]

## VIII.

Access to the basement is obtained by a stone staircase, situated under the main one, and opening from the assistants' corridor. At the foot of these stairs, and for the convenience of the said assistants, an apartment for their use as a cloak room, and leading from it is a lavatory fitted with hot and cold water for washing purposes. This is not being a suitable position for a sanitary convenience, the lavatory for the assistants' use has been placed by the back staircase, under the covered way, where it receives light and air directly from the open. The assistants' room and lavatory receive some borrowed light both from front and back, but would need to be principally lit by electricity, which, however, would not be in use for any long time during the day.

Better situated as regards its lighting is the front portion of the basement, which has, therefore, been appropriated for the packing, making and storing room, and which, as will be seen from the plan, elevation, and section A B, has a well illuminated bench beneath a large window, the latter being partly above the pavement level and partly in a light well, lined with white glazed tiles; as would also those in the yard, one of which affords light to the heating chamber, where would be situated the furnaces and boilers for the general hot water supply and heating of the whole establishment. The coal store in connection with this will be found alongside the packing case room, where it can receive its supplies by a glazed coal chute and shoot direct from the street, as shown on the ground floor and basement plans.

The lift might be either an electric or hydraulic one, as found most convenient; in either case its motive apparatus finding a place under the main stair well, in the angle of the basement stairs, as shown.

Passing round it, we find ourselves in a passage, lighted, as shown on the basement and ground floor plans, by pavement lights in the floor under the covered way above, and leading to the enlargement making and developing rooms. These have been put in the basement, because they do not require any daylight illumination, and because they would there be most free from the vibration which is so frequently caused in the upper parts, especially of town buildings, by the passing of heavy traffic. For this reason also these rooms have been placed as far back as possible from the street, and with their solidly built foundation walls and concrete floors should be immune from the trouble referred to.

As will be seen, there are two of these apartments, one devoted to bromide work and the other to the making of enlarged or reduced negatives, and lantern and other transparencies. Each has its own developing room, fitted with benches and sinks, hot and cold water, and red, yellow, and white electric lighting, to suit the operations to be performed in them. The developing rooms would be shut off from the enlarging ones by double doors, as also the enlarging rooms from the electric light chamber between them; while safe ingress and egress are also similarly provided for by the separate doors leading into the corridor. The electric light chamber would, of course, contain the large arc lights for enlarging purposes, the enlarging cameras being fitted against the walls in the enlarging rooms on each side, in line with the sets of rails which are shown on the floors for carrying the enlarging easels. The whole basement could be lined throughout with white glazed bricks, in the front rooms and passages, for increasing the illumination, and in the developing rooms for promoting cleanliness.

Going up again to the ground floor of the back building, we find ourselves in the covered way, which affords convenient access to all the ground floor rooms and to the staircase to the upper portion, and, by means of the pavement lights in its floor, gives light to the corridor below.

Next, we have the silver toning and platinum developing rooms, in convenient proximity to each other, and, although connected, each having a separate entrance of its own. Both are lined with white glazed bricks, both fitted with benches and Doulton sinks, and both also having concrete and cement floors, slightly sloped to central

drains for the carrying off of splashes, easy cleaning down, etc. Each would also be fitted with coloured electric lights for night work, but as the operations carried on in them can also be executed by tinted or subdued daylight, they are also provided with windows, which would have sliding shutters of glass or fabric, and which are protected against too much light by their position under the shadow of the covered way.

At the end of the latter are the frame-making shop and the moulding store, the former situated where it will get a good light upon its window bench, and the latter being placed in the angle, where it can only receive borrowed light through its own glass door and from the staircase, because the good lighting of such a store is not essential, and an electric lamp, to be switched on and off as required, to place or remove the lengths of moulding in or from the racks, would be quite sufficient.

Ascending the stairs, which, as will be seen from the plans, and from the Sections A B and C D, are very well lighted all the way up, we come, on the first floor, to the packing and forwarding, and mounting and finishing rooms. In some respects these would have been better on the ground floor, as there being nearer to the reception room and the goods entrance, but in the space at our disposal, and in view of other conditions, this was not possible, so they have been placed in the present position, where they enjoy the advantage of a better light than they would otherwise have done, and where they can still be reached from the reception room, the general office, and the goods entrance passage, by the door upon the second half landing of the main staircase, as well as by the back staircase from the other work rooms. They would be fitted with benches, shelving, and cupboards, as shown.

On the other side of the stairs are the mount and general store, and the plate and paper store, the former being given the daylight position and the latter that in which only borrowed light from the staircase is possible. Even this illumination could be easily blocked out with a shutter of red or yellow fabric, when it was desired to open or examine plates or paper by a non-actinic light. In this position also plates and paper could be quite safely stored away from chemical or other fumes and emanations, such as might be found in some other parts of the establishment. Benches and shelving would be provided as shown, and the doors of both these rooms be fitted with duplicate keys for the use of the principal and of the storekeeper, whose business it was to take in, give out, and account for their contents.

Ascending to the second floor, we find, over these rooms, the chemical store and laboratory, and the carbon sensitising and developing room. The former of these is a very convenient place to have, inasmuch as in it all chemicals in bulk can be kept under lock and key, and where their fumes and emanations are well away from plates and silver paper. In it chemical apparatus, scales and weights, measures, etc., would be always ready for use in compounding all developers, solutions, etc., in an absolutely correct and uncontaminated condition. Such a room is also very useful when it is desired to do any special experimental or testing work which cannot be conveniently carried on in the midst of the ordinary routine proceedings of a large commercial establishment. It would be fitted with sink, benches, shelving cupboards, etc., as shown, and have a good light from its large window. Next to it we have the carbon sensitising and developing room, placed in the unlighted angle of the site, because the operations to be therein performed are independent of daylight, and would all be done by the coloured electric light which would be fitted, though some borrowed daylight could be obtained for cleaning or other purposes by the usually shuttered window on the stairs, as seen on the plan and the Section C D; benches, Doulton sinks, drying cupboards, racks, etc., to be fitted as shown or required.

On the other side of the landing we have the negative store and the retouching room. These are naturally kept together, and thus high up in the building, for the sake of obtaining a good north light for the windows of the latter, under which runs a bench, to accom-

modate four retouchers, one at each window opening. The bench under the window of the negative store would be used for work on the back of the negative, and similar processes, while on the small bench in the retouching room would be fixed an electric stove, to facilitate varnishing without dust, for the more easy elimination of which latter the floors of these and other work rooms would be also covered with linoleum, to allow of easy and thorough cleaning. On the walls of these apartments would be fixed shelving, as shown, to accommodate negatives of all the standard sizes, of which there would be space to hold many thousands; while provision should also be made for the orderly keeping of the indexed and illustrated registers which should accompany every well-kept stock of negatives and render them easy of finding and identification.

On the next floor above is the artist's studio, kept right at the top in order that it may receive the best possible north light to its side and top windows, as shown on the plan, the Section A B, and the roof plan. Here would be done the finishing of all enlargements, colouring, miniature painting, etc. A convenient bench, with cupboards under, runs round two sides of the room, with a small useful sink in the corner for washing hands, brushes, etc.

The rest of this floor is occupied by the printing department, including the sensitising and changing rooms, which are enclosed by orange glazed partitions under the slated portion of the roof, and

the printing place proper, part of which, as will be seen by the plan and by the Section A B, is under the glass roof and part in the open. The latter portion is enclosed by a dwarf wall, round which is a bench for printing frames, while in its centre is a printing table running on rails, so that in the event of a sudden shower it could be immediately pushed in under shelter of the glass roof as shown.

Having now completed our description of the building and stated the reasons for placing the different apartments in the positions they occupy, both as regards the general planning and their relations to each other, thereby, I hope, elucidating some of the general principles of the subject, it now only remains to note that the present structure has been designed for execution in red brick with stone dressings, with the exterior woodwork of oak, left from the tool and well oiled. The leaded glazing of the casements and fixed lights would be in steel or gun metal frames, and the ogee roof of bay in copper. The scroll and motto, "Per luce vivamus," would be in cut brick, with the letters gilded to match the gilt copper of the device of the flaming sun above; while the symbolical figure of Light crowning the gable would be of stone, carrying a copper gilt electric torch, which could be switched on when the electric light studio was in operation, as a general advertisement at night. The cost of thus erecting a building of this extent and fitting it as shown on the drawings may be roughly estimated at £3,500. DRINKWATER BUTT, F.R.P.S.

## THE CAMERA ON THE JOB.

[An article in "System" on the value of photographic records in business, the purposes they can be made to serve, and systems used by contractors and manufacturers for securing and keeping them.]

A RECORD of every important detail of business—a record that has a meaning and a use—that is one of the purposes of system.

Business to-day is developing a new kind of record—automatic, accurate, incontrovertible: the photograph. To manufacturers and builders, to engineers and contractors, who are carrying out the same constructive enterprises of the day the photograph is coming to be a most important record.

To these men, who are accustomed to handling reports, drawings, profiles, and blue prints, from one end of the day to the other, it is a positive relief to have a superintendent send in along with his report a photograph of the work as it actually stands when the report is made. And then, too, it verifies the report. Even the superintendent with the best of intentions is likely, at times, when the work has dragged, to convey the idea in a written report that more has been done than is actually the case. A photograph cannot very readily be made even to imply an untruth. And if the superintendent knows that a photograph must be taken at a certain time, he will put forth his best efforts in order that it shall show as great an amount of progress as possible.

The Arnold Company, of Chicago, on all its work takes photographs at uniform intervals of two weeks. These are all made in a uniform size of 8 x 10 inches, and with progress blue prints of the same size they are fastened with eyelets in a heavy paper cover. These covers have printed on the outside the name of the job, date, name of customer, and location. Several sets are made up for each date. The covers are printed in quantities, the printer changing the date for each set. One of these sets is kept in the files of the main office, and one set at the office on the work. One set is also sent to the person for whom the work is being executed, or to each of them if there are more than one. A few are kept on hand for emergency and to show to prospective clients.

### The Usual Method of Securing Photographs of Work.

A contract is made with a local photographer in each place where work is to be prosecuted. This contract specifies the exact size plates and prints are to be, colour, style of finish, and mounting, price for plate, and price for prints. The plates in all cases remain the property of the company, and the photographer is not allowed to sell copies without permission. This is readily granted in most cases, however, and brings an added income to the photographer; he is also allowed to place his imprint on the back of each photograph. For these reasons an advantageous rate can usually be secured from the photographer.

Where photographs are 10 x 8 inches or larger, most contractors prefer to have them mounted on muslin, with a hinge and extension for binding. Sometimes this is done on the smaller sizes, though these are more frequently printed on ordinary paper and mounted in an album, such as can be secured of almost any dealer in photographic supplies.

One of the higher refinements of photographic work has been worked out by one of the engineers of this company in connection with the construction of the shops of the St. Louis and San Francisco Railroad at Springfield, Missouri. Here, instead of a hit-and-miss system of taking anything which seemed to be of value from an desired point, the company established four points on the job from which all views are taken.

The ground on which the shops are being located is a rectangular piece about forty acres in extent, and has a considerable diagonal slope. At each corner of the rectangle a substantial but inexpensive tower was erected, the four of varying heights above the surface of the ground but all uniformly thirty feet above the grade on which the buildings were to be placed. The buildings were to be six feet high, so that a camera placed on any one of the towers would cover the buildings without distortion.

### Photographs taken with the Accuracy of a Surveyor.

A point was established on each of these towers, and an arrow of direction. The photographer was required to adjust his camera to these each time an exposure was made, almost as accurately as a surveyor would adjust an instrument in striking a line. These stations are lettered A, B, C, D; the proper letter is put on the negative in connection with the serial number. These photographs taken from the same identical points each time, enable one to see the building grow before his very eyes, almost like the film of a moving picture machine. In addition to the views taken from the towers, detail photographs were also taken of important parts of the construction.

The method in use by the Frank B. Gilbreth organisation has long since proved its efficacy. It consists of a set of private instructions published in a little book called "A Field System," which contains all the regulations and instructions of the organisation to its employees. The uses of photographs other than their merely casual and incidental application, are stated as follows:

"For keeping office employees in touch with varying conditions which from time to time obtain on the various jobs.

for indisputable records of the condition of adjoining buildings before starting work, and after its completion.

Photographing cracks over doors and windows and in other places to show whether or not any settlement has taken place, due to the construction work involved.

For records to be available in case of a law suit or other discord and misunderstanding.

For advertising purposes."

Various other rules, as follows, indicate the methods of procedure in photographing, which have been found to be most advantageous in obtaining the pictorial record desired:

In all cases pictures should be taken of the men while at work, not as though idle and posing for a picture. On out-of-town work, negatives should be mailed to the New York office, and the negatives should be promptly sent to the regular photographer employed by the firm.

All negatives should be dated and numbered. Prints should be mounted, and Velox paper should be used for all prints. The method to be used on all photographs is as follows: the proper contract number, serial number and date being inserted in the place indicated:

By the regular photographer: A 31-32-5-16-06; by the employees on the job, when taking photographs which are developed by the regular photographer: A29-J 32-4-20-07; by the regular inspector or others: A 28-B-5-20-06.

Photographs should be marked in no other way. If possible, keep outsiders out of the picture. As soon as a film is taken, mark on the outside of the wrapper that surrounds it the contract number, date on which the picture was taken, and the name of the person taking the picture, sending the film, thoroughly wrapped up so as to exclude the light, to the regular photographer. Special stress is to be put on the advisability of obtaining photographs of conditions at the scene of any accident. Unless otherwise directed, at least one roll of film should be taken on each job, each week, and all pictures on film should be taken the same day.

After the film is removed and sealed, the contract number and date of taking photograph should be clearly written upon it.

Care must be taken to use the 'J,' 'B,' or other serial letter, so as not to duplicate the numbers on pictures already taken."

### **Smallest Details are Recorded in the Form of Pictures.**

These pictures show in detail how the forms were made, even to numbering on the forms. They show as well the construction of the columns, which splice plates were riveted in the shop and which were riveted in the field, and the condition of staging and its proximity to the adjoining structures. Some of the columns shown in the Gilbreth photographic files were 7½ tons in weight, and by means of such photographs it is accurately shown how long the columns rested on the ground before being set in place. They also show the condition of the work, and consequently whether or not the contractor was able to take care of these columns immediately after delivery.

In its working application, the Gilbreth method of photographic record has been found through its check upon the work of the employees, to prevent damage to owners, to adjoining property, and to the contractor's interests, and to prevent legal disputes, as well as furnishing the data necessary to settle them without delay.

Many engineers and contractors require two classes of photographs to be taken on all pieces of work: construction photographs, which are kept for record of the method and progress of the work; and what may be termed "publicity photographs," kept for showing the class of work the firm is engaged in, thus influencing prospective clients, and for advertising purposes.

Among firms following this method are Dodge and Day of Philadelphia. Each of their superintendents of construction is provided with a film camera taking a photograph 5 x 4 inches. At regular intervals photographs of the work in progress are made, a placard giving the name of client and date having been placed on the work.

The film is returned to this office, and two prints of each negative are made by the firm's photographic department. The films are kept on record in that department. Consecutive numbers are given each plate, regardless of what job it comes from; each job is given a letter, which is prefixed to the number. One print is kept at this office and one print is sent to the superintendent on the work. The

print in the office is properly filed under the letter and date in a cover provided for that purpose.

### **Photographs Aid in Publicity and in Securing Business.**

The publicity photographs are taken on 10 x 8 in. size by the firm's regular photographer, at such intervals during the course of work as will ensure interesting pictures. These plates are given consecutive numbers, and a blue print of each plate is kept on permanent file in the home office.

While this primary purpose of these photographs is a record of progress and as publicity material, they are valuable evidence in case of disputes; and, more, they often act as a sort of police power in the prevention of litigation. The knowledge on the part of a sub-contractor that the general contractor has dated photographs of the work on which he has been employed, will tend to discourage the presenting of unjust claims. Cases of dispute which have come up, and which would otherwise have gone to court, have been satisfactorily settled when the photographic records were referred to.

If a company employs its own photographer, there is an advantage in having a man who has some knowledge of engineering. In fact, some concerns consider an insight into engineering problems of more value than an expert knowledge of photography. For securing its photographic records the George W. Jackson Company, of Chicago, had in its employ a man of some technical training who is an amateur photographer. He is engaged continually in visiting the different pieces of work which the company has in hand, and in addition to the photographs which he takes he is able to report on any features of particular interest or answer intelligently any questions which the pictures may suggest to the engineers of the company. Each piece of work is visited about once in two days. The photographer immediately develops his plates and makes prints on developing paper, so that when Mr. Jackson comes to his office each morning he finds on his desk a photographic representation of a large part of the work as it looked the day before. The photographs are preserved in albums, with a notation under each.

In the factory the camera can be adapted to an endless variety of uses, limited only by the ingenuity of the manager in applying it and the skill of the photographer in working out practical applications. Here the photographer in a large number of cases is a regular employee having rooms assigned to him in the plant, and occupying a permanent place on the pay-roll.

In the shops of the Power and Mining Machinery Company of Milwaukee the first machine of a new design or type is always photographed when assembled, and photographs of it are sent to the different agencies to keep them informed as to what is being manufactured.

Some of the firm's customers, especially those who are located in foreign countries, demand that each machine be photographed to show that it was assembled. These different machines are photographed individually and from different points of view, so as to distinguish one from the other. Photographs of these different views of different machines are mailed to the customer and are invaluable when erecting the machines.

### **The Increasing Demand for the Camera in the Factory.**

This company also photographs drawings which are sent in to figure from and which must be returned with quotations. By this method the manufacturer insures himself against the customer substituting another drawing of more expensive construction, and can refer to the photograph at any time a question arises as to methods of figuring, and other matters, before the contract is closed.

Similarly for protection photographs are taken of the surroundings of a machine when an accident has taken place. This is always done before the parts are disturbed, so that it may be used as evidence in court. These photographs have very often indicated that the person hurt was at fault.

General drawings and special details of machinery on price book pages may very well be photographed in order to facilitate explaining the construction of the firm's manufactured goods to the customer. This saves the annoyance and trouble of carrying around large blue-prints which must be folded or rolled up, and which, after being used several times, become torn.

Photography can very advantageously be used for preserving and

duplicating confidential records. The Power and Mining Machinery Company reproduced their price list in this way. And in view of the fact that this price book must be revised very often, it is also found to be economical and more convenient, besides more rapid, to typewrite the pages on ordinary commercial paper, and then photograph them down to the proper size sheet for the price book. In this manner a large amount of information can be crowded on a small sheet (necessary because the book is made pocket size) and the characters are very clear. By doing this work themselves instead of handing it to a printer they are absolutely sure that the price sheets do not get into the hands of competitors, as the number of copies is kept track of in the photograph room.

The Allis-Chalmers Company attempts to secure a complete set of views for each installation of equipment made. These are used in the sales department as aids in planning tentative lay-outs for prospective customers.

Every salesman knows that if he can show a customer just how a thing is going to look when completed he has gone a long way toward awakening the interest which leads to a sale. Especially is this true in an elaborate lay-out of electrical apparatus, about which the purchaser sometimes knows little and feels a large degree of uncertainty. The publicity department of this company also makes extensive use of the photos of completed installations. Articles are

prepared by the department's technical writer describing the equipment in detail. This article is mimeographed, and a copy, together with a set of the views, sent to a large number of publications likely to be interested. The Allis-Chalmers Company has developed an advertising function of photographs to the utmost.

Photographs of important pieces of work are taken as progress through the shop, as, for instance, the group of views of a steam turbine in different stages of completion. They are used to familiarise those in both the mechanical and business departments with the work which is being done, as well as to assist in accomplishing the other work which have already been mentioned. Copies of all photographs are filed in a vertical file in the photographic department. For this purpose they are mounted on a piece of white 6-ply cardboard  $8\frac{1}{2} \times 11\frac{1}{2}$  inches in size. The prints are attached only at the top edge, as pasting over the entire surface would inevitably cause warping of the cards, making them very inconvenient to handle in the file. The upper margin of the card is printed with suitable blanks for records, as shown in the reproduction. They are the most part, indexed under the name of the installation—"Patapsco," "Kern River," and the like, and as well as being cross-indexed for the kind of equipment, as "Steam Turbine," "Dynamos." E. S. HANSEN

## THE COLOUR-FILTER AND THE "ISOCROMATIC" PLATE IN ASTRONOMICAL PHOTOGRAPHY.

[The following paper, by Mr. R. J. Wallace, read before the American Association for the Advancement of Science, is primarily addressed to astronomers, but as it is a scientific and most lucid exposition of the principles of orthochromatic photography, it affords a fine space for it in our columns, and we commend it to the study of any who may have been confused by some of the indiscriminate writings on the subject of which there has been no lack during the past few years. We are indebted to Mr. Wallace for certain of the diagrams which illustrate his paper.—Eds., "B.J."]

THE new era in photographic science, opened by the introduction of the (so-called) isochromatic plate and its accompanying colour-filter, was pregnant with significance to astronomers in general throughout the world, for hitherto while the application of photography to the recording of results could be attained only by the possession of an expensive correcting lens, the simple combination of a colour-filter and isochromatic plate not only fulfilled all requirements, but did so more perfectly.

It requires but little consideration to arrive at the very logical conclusion that, whether an individual be equipped with but rudimentary photographic knowledge or an extended experience, successful results are more or less a matter of "accidentals." Natural causes compel that this must be so, i.e., the unsteadiness of the earth's atmosphere, and consequent "bad seeing." Every astronomer knows that during the period of an observation there are moments when the image appears to "steady down" and detail "flashes out," only to be again lost in the ensuing "boiling." In the case of a large image like the moon, these moments of steadiness can be watched for and taken advantage of when they occur; but, naturally, it is the exposure of plate after plate, or the exposure of portion after portion of the same plate, that gives results, because it is obvious that, given even fairly good seeing, the development of a large number of exposures taken consecutively throughout the period must result in some that are much better than others, since the better ones utilise the light during a momentary steadiness. It follows, therefore, that the steadier the air, the greater the percentage of good images, and the greater the number of exposures, the better the chance for success.

Assuming the possession of a telescope, a colour-filter, and camera-box, together with a plentiful supply of plates and a modicum of manipulative photographic knowledge (which is not synonymous with a knowledge of photography), there are but few things less difficult than obtaining results in so far as the operator is concerned; the only element of uncertainty introduced being the atmospheric disturbances, over which he has absolutely no shadow of control. The focus is fixed by star-trails at any time prior to the exposure, and, once determined, it remains constant except for temperature, which by contraction or expansion of the metal parts of

the telescope, or change of figure in the objective, shifts the plane nearer to or farther from the objective. Several settings, however, at varying temperatures provide points upon which, if erected a focal curve, the casual observation of which, before or during work, instantly indicates the exact focal setting.

It is an almost incomprehensible fact that while the principles underlying the use of colour-filters and "isochromatic" plates are very thoroughly understood by all students of photography, yet astronomical circles generally the most vague and visionary ideas are entertained, and this, too, in many cases, by the very individuals who are making constant use of both. It is unfortunate that data relative to the subject is almost wholly scattered throughout the photographic and other journals (mostly European), and so it has been written by so many people, that to attempt the correction and necessary editing of the material would be a task herculean. The purpose of the present paper, therefore, is to attempt to set forth connectedly the principles governing their use.

In the adjustment of a colour-filter to a visual refracting telescope the point of first consideration is the correction of the lens colour, i.e., the "colour-curve." Generally speaking, the curve from  $\lambda 5400$ - $\lambda 5900$  represents the portion most nearly flat, viz., where the rays approximately come to the same focus, while the points of different wave-lengths lie at a gradually increasing distance apart. As a typical example of a visually corrected objective, the colour curve for the 40-in. telescope is shown in Fig. 1.

If all light-rays passing through the objective were to converge to a focus at the same plane, then of course the colour curve would be represented as  $f$ , and when photography was attempted it would simply be sufficient to place in that plane a photographic plate whose selective sensitiveness it would not be necessary to consider.

Strictly speaking, there is only one point upon the curve where  $v$  is directly coincident with  $f$ ; but generally speaking, and in practical consideration, a much greater extent is permissible, this extent being limited by the diameter of the confusion circles, which themselves are dependent upon the angle subtended by the object.

In the case of the 40-in. telescope the angle subtended at the visual focus equals almost  $3^\circ$ . Considering the light-ray at  $\lambda$

indicated on the figure by an arrow) as forming a point source at plane of the plate at  $f$ , it will be seen that the different focus points of different wave-lengths will be spread out into confusion circles of greater or less diameter as the rays cross nearer to or further from that plane. Light, therefore, of  $\lambda 4800$  and  $\lambda 6700$  will spread out from a point source into a circle whose diameter is about  $0.7$  mm. As the intensity of the light is diminished in inverse proportion to the surface, it follows then that a light-intensity of unit value at its focal point must possess a weakened photo-chemical value according to the distance the plate is removed from that focal point. Hence it cannot produce the same effect on a photographic film unless the time of exposure be proportionately extended, such extension from investigations by Abney,<sup>1</sup> Schwarzschild,<sup>2</sup> Mees and Sheppard,<sup>3</sup> and others, being represented by  $I \times t^p$  the value of the exponent<sup>4</sup> being less than unity, and varying with different plates. In all probability it also varies with the wave-length.<sup>5</sup>

The value or amount of this weakening of the light is, however, dependent upon another factor, and that a most important one, the sensitiveness of the plate to the wave-length in question.

Fig. 1.

portion of the colour curve which approximates a straight line in the very region to which the ordinary photographic film is directly insensitive, and hence enters the isochromatic plate. It is an interesting coincidence that it is just thirty-four years that the first publication was made in English of Dr. H. W. Vogel's discovery on photographic sensitiveness to rays of longer wave-length than the blue, by the introduction to the emulsion of sundry dyestuffs and also the first use of a colour-filter. Vogel's original announcement was made just one month prior. It does at first sight appear somewhat strange that, in spite of the almost immediate and since continued activity of the plate-manufacturer, commercial "iso" or orthochromatic plate of to-day is practically but a very slight advance upon the primary discovery. It is nevertheless a disagreeable fact.

The difference in selective sensitiveness between the ordinary and the isochromatic is plainly shown in Fig. 2, which illustrates graphically the sensitiveness curves of a Seed "27" and a Cramer instantaneous Isochromatic."

It will be noticed that the "iso" plate possesses a secondary maximum at about  $\lambda 5600$ , which is approximately even in intensity from  $\lambda 5300$  to  $\lambda 5700$ , a most convenient coincidence, as this region corresponds precisely with the flat portion of the objective colour curve. It results, therefore, that if the isochromatic plate be placed in the plane of  $f$ , the secondary sensitiveness of the plate and the focus for the yellow-green rays are coincident. It is of course true that all of the wave-lengths between, say,  $\lambda 5200$  and  $\lambda 5900$  do not come to *precisely* the same focus, but they do so with practical identity.

The strong maximum at the blue end of the isochromatic plate

Fig. 2.

is an unfortunate condition which up to the present has not been susceptible of much improvement. It does not exist from lack of effort to remove it, because both the plate-manufacturer and the independent investigator have devoted much time to its subjection, but without satisfactory results; for while it has been possible to lower it by the introduction to the film of otherwise inert dyes whose absorption corresponded with the blue maximum, yet it has

Fig. 3.

a. Cramer instantaneous isochromatic unscreened.  
b. Cramer isochromatic increasing exposures through colour-filter.

been at the expense of speed, which is thereby greatly lowered. The Cramer "slow iso" is typical of such a plate.

It might at first thought be considered possible (and several astronomers have attempted) to make use of such a stained plate in astronomical photography; but it must be remembered that, although the sensitive film may be so loaded with dye as effectually to filter out the over-active blue-violet rays from the light transmitted by it, yet on the surface of the film the particles of silver bromide are covered with a layer of dye of extreme attenuation; hence there would always be action by the blue-violet light

<sup>2</sup>Astrophysical Journal, 11, 89, 1900.

<sup>3</sup>Theory of the Photographic Process, p. 214.

<sup>4</sup>Where  $I$  = intensity, and  $t$  = time of exposure.

<sup>5</sup>A. Becker and A. Werner, "Das photographische Reziprozitätsgesetz für sensibilisiertes Gelatin bei Erregung mit Licht verschiedener Wellenlänge," Zeitschrift wissenschaftliche Photographie, 5, 382, 1907.

although in a lessened degree, which would result more or less in submergence of the sharp image under a veil of confused out-of-focus light of comparatively great actinic energy. The out-of-focus red light at the other end of the curve need not be considered, as the plate is insensitive to radiations of this wave-length, even with very prolonged exposure. The only practical method for the elimination of this out-of-focus blue-violet light is by the employment of a colour-filter which will absorb it before reaching the sensitive film. It is axiomatic that pure monochromatic light acting upon the plate will produce the sharpest image.

Not only is it impossible to construct colour-filters to transmit true monochromatic light, but even if it were possible they would be valueless, because the light transmitted would be too feeble to be effective. They are constructed, therefore, to absorb all wave-lengths shorter than from about  $\lambda 4600$  to  $\lambda 5400$ , depending upon the class of work for which they are to be used. It is necessary, generally speaking, to have a colour-filter with a closer approximation to monochromatism when engaged in the photography of faint detail. This is a point well understood by all experienced photographers, and approximate monochromatic light-filters in photo-microscopy have been used a greater number of years than I would care to go on record as quoting. Such filters

have also, for some time, been a regular article of commerce. There is a great deal of uncertainty relative to the absorption of a certain colour-filter, and it may as well be stated now that photographic absorption of a colour-filter, with a certain plate, depends upon the exposure which that plate receives. Increased exposure means increased extent of action. This is true of all filters (see Fig. 3).

The best position for the colour-filter is immediately in front of the sensitive plate. In such position it is known that it displaces the image by a distance equal to  $t \left( \frac{\mu-1}{\mu} \right)$  when  $t$  is the thickness and  $\mu$  refractive index; hence it is necessary, for this cause at least, to determine the position for a new filter before exposure is made. For critical work it is necessary to determine focus separately for two colour-filters, even should they possess practically the same absorption, because in manufacture, no matter what amount of care is used, small differences are unavoidable.

If the filters possess different absorptions, then it requires more than a primary knowledge of that and the objective's colour curve to know that the focus must necessarily be different.

ROBERT JAMES WALLA

(To be continued.)

## ON THE SIZES OF STEREOSCOPIC PRINTS.

(From the "Photo-Revue.")

M. LIHOU, President of the French Stereo Club, in a recent article on the "Æsthetics of Stereoscopy," well said that "the beauty of stereoscopic prints is intimately connected with their size." And, further, addressing himself to those who adhere rigidly to the same size, he adds a caution as to falling into a groove when following this branch of photography.

It is easy to show that in adopting the square form of stereoscopic prints, obtained with lenses the focus of which exceeds about 4 inches,

The images obtained will then be  $a, b$ , and  $c, d$ . Taken in these conditions they will partially coincide with each other, and be limited at their point of contact by the line  $h, e$  (the line of separation), which thus compels us to dispense with the two portions of the image  $e, c$ , and  $e, b$ . The points of view being in  $o, o'$ , should be equal to  $o' e$ , and  $o f$  to  $o e$ , so that the parts  $o, g$ , and  $g d$  will be also sacrificed. There remains, therefore, the portion of the image included in an angle of 26 deg.—namely,  $f e a m$ —the width of which corresponds to the separation of the lenses. Under these circumstances the whole height at disposal, equal to the line  $a b$ , can be given according to the subject, instead of limitation

Fig. 1.

the photographer is compelled to sacrifice part of the image in the direction of breadth, and he usually, by his own will, dispenses with an equivalent portion in the direction of height, so that of the total image,  $a, b, k, l$ , Fig. 1, given by the lens, only the square centre  $a^1, b^1, k^1, l^1$  is retained, the rest being rejected. If, in the interests of the whole, we are able to gain in height what is lost in breadth, we should employ every possible means to gain this end. Assume that the two lenses,  $G, D$ , placed at a distance apart of 70 mm., and each of the focus of 6 inches, cover an angle of 58 deg., the diameters of the fields will then be about  $6\frac{3}{4}$  inches, and the squares falling in this circular field will have each side about  $4\frac{3}{4}$  inches in length.

Fig. 2.

height to the dimension  $a^1 k^1$  actually adopted. The print obtained will be  $f, e, n, m$ . The more the lenses are separated, the less do the two fields overlap, and the greater the width of the image is permissible. This latter will be limited by the separation of the eyes, which should not exceed 70 mm. ( $2\frac{3}{4}$  inches), otherwise it is difficult to unite the two pictures. From Fig. 1 it will be understood that the separation of  $2\frac{3}{4}$  inches is the most suitable for most sizes, and why also the space left between the two pictures of a stereograph has no object, in fact. There being an image at  $e, e, b$ , our desire is to utilise the whole of it and not to suppress it. Quite otherwise is it in the case of small stereoscopic prints obtained with the apparatus fitted with lenses of from 2 to  $3\frac{1}{2}$  inches.

where the square fields given by the lenses do not overlap. In the case of a focal length of 55 mm. (about  $2\frac{1}{4}$  inches), and a field of 55 deg. (Fig. 2), the images  $r, s, r^1, s^1$ , will have a diameter of squares inscribed in circles, and will measure on each side about 45 mm. (about  $1\frac{3}{4}$  inches). We shall consequently be able to see before our eyes the entire images, having an angle of about 45 deg., and not two truncated images, giving us an angle of only 22 deg. as in the preceding example. The shape will necessarily be rectangular, although by the use of masks we can obtain a shape of height in reference to the width as may be necessary, without loss at the expense of part of the image.

space  $m, n$ , between the two images can be varied without affecting their size. And the separation of the lenses can be modified to suit the user's eyes to 63 or 65 mm. The perspective in this will be better and the result obtained more natural. The advantage of the small apparatus is undeniable, apart from the very compact form which the small size gives to it. The wide angle of view is, however, of the greatest interest. If, by increasing the focal length of the lenses, we increase the height of the images, we will increase their breadth at the same time, and the images will then square up to the point at which they meet, after which the height alone can be increased in proportion to the covering power of the lenses, whilst the angle of view included in the direction of the view will decrease in proportion. The maximum focus giving sharp prints which join exactly is about 9 cm. (just over  $3\frac{1}{2}$  inches), and the angle of view of 58 deg. The diagonal being 4 inches, the height will be 7 x 7 cm., if the separation of the lenses is 70 mm. judgment the 9 x 15 plates, or 10 x 15, should give the best results for mounted stereoscopic prints. We say 15, in order to facilitate mounting, the print should have a width of exactly 7 cm. of 11 or 12 cm. focus will thus allow of the camera being made in a very portable shape, and the prints will be from 9 to 10 cm. (inches) high.

Eye-pieces of stereoscopes generally in use cover much too small an angle, with the result that when viewing prints which are less than 7 to 8 cm., the distortion is visible to the detriment of the result. Another drawback is the impossibility of viewing with the eye-piece the prints obtained of size 9 x 18. As the height of the pictures increases, their points of view being no longer on the same plane as the lenses, the upper part is greatly distorted. It should be possible, however, to remedy this defect by providing an adjustment of the apparatus by which a panel carrying the two lenses could be moved up and down, an addition to the stereoscope which would allow of prints of any size being observed.

L. STOCKHAMMER.

## Exhibitions.

### THE PORTRAIT WORK OF FURLEY LEWIS, F.R.P.S.

A photographer is so clever at his work that the risk of failure is unknown to him, his exhibited results are likely to suffer from this, and that is, the dreaded dead-level. A dead-level of excellence is only one degree less uninspiring than a dead-level of mediocrity, because, in all things, the unco' guid cannot come to the sympathies of those who struggle and sometimes fall. As we round the gallery at 66, Russell Square and contemplate the masterly photography of Mr. Furley Lewis, one almost longs to go from the high standard. In this one respect Mr. Lewis is at a disadvantage. His works are all of one style—all but a very few of ladies; their scale is, generally speaking, the same, and the method of presentment similar. In spite of this, nevertheless the exhibition is admirable, simply because, in these several instances, one sees that a fine taste has proved all things and kept all things.

There are no rash attempts at singularity, no wild experiments in colour, mounting, scale, lighting, definition, and so on, which in other exhibitions have sometimes evoked more than pleasure. An unexceptionable method having been adopted, it is thenceforward adhered to. That Mr. Lewis is a professional, rather than an amateur, may be due in part to that fact. He is a Bohemian artist, whose attitude to his work is almost unique. A goodly sprinkling of the portraits are evidently never taken as profitable commissions. His more the rendezvous of people of interesting temperament in a reception-room of a commercial portraitist. No doubt

many other photographers would be glad of the same free and easy methods of work and the same immunity from the worries of a properly conducted commercial establishment, and under such conditions many might perhaps be found to do equally admirable work. But there is not room for many such, and, after all, the fascinating personality of Mr. Lewis is a business asset denied unfortunately to all but a very few.

Of the well-known faces in the photographic world which figure here the majority of visitors will be able to judge from their own personal knowledge. It will be seen how very cleverly the character of each is suitably kept in view in the posing and lighting. Compare, for instance, the portraits of the very first two on the list, Rev. F. C. Lambert, and F. J. Mortimer. But of one or two others who are not photographic celebrities, the writer of this can add his unhesitating testimony as to the successful seizure of the quintessence of the sitter's personality. In the portrait of the gigantic Niels M. Lund, for example, the strength of the painter is felt as much in the hands as in the head, and even his coat has a force that belongs to its wearer. Another painter, the late H. G. Moon, is shown with even more intimate knowledge and understanding. His strong, keen, and kindly face is a triumph of powerful modelling, and his nervous hands are made much of. The pose is at once animated and restful—a pause between the puffs at his pipe whilst he listens to a friend's remarks. This is perhaps the finest thing in the exhibition; its breadth and choice lighting could not be surpassed. The silver-haired Dr. Howard Barrett, energetic and precise; the genial Oscar Arndt, with fuller locks of the same brilliancy; the homely and rugged face of Prince Kropotkin, each of these are veritably to the life, and in no way whatever beautified for commercial expediency. Not even the little picture of the photographer's own wife and child owes its charm to anything but pure and unadulterated photography.

In the portrait of Mrs. Lund there is a departure from the generally adopted method; for the lady's head is lit from behind and above, being itself in a flat tone, delicately differentiated from the tone of the background, and edged with light upon the hair, neck, and shoulders. This is a very lovely essay in light. "Colleen" also is a delightful study of a head of unmistakable Irish beauty. It has a fascinating tilt backwards, being in profile. The beauty of this as a mere print, apart from its subject, is noteworthy.

The visitor should not omit to study the fine profile of Terence O'Brien and the splendid expression and mastery of a difficult pose in Reginald Dance. Mr. Furley Lewis is to be congratulated upon the quiet and dignified excellence of all his portraits.

F. C. TILNEY.

THE Manchester Amateur Photographic Society have opened an exhibition of 120 oil prints in the society's rooms in Market Street. Mr. S. L. Coulthurst shows a charming lakeside view which resembles an etching very closely, and Mr. Harry Holt (Rochdale) and Dr. A. T. Lakin have portrait studies. A close examination of Mr. C. F. Stuart's (Liverpool) "Young April" will repay the beginner who desires to rise above the commonplace in composition and rendering of atmosphere. Another Liverpool exhibitor, Mr. J. D. Johnson, reaches a high level in his "Snow in the City." Mr. J. W. Atherton (Tudmorden) might be more successful if his impressionist ideas were less deeply ingrained in his work. Three pictures are shown by Mr. G. E. H. Rawlins, to whom may be credited the introduction of the oil-printing process. Miss Stevenson's "A Portrait" is one of the best things in the exhibition, although probably more attention will be called to the colour work of Mr. E. Warner (London), who in "Fowey Ferry" has treated his subject charmingly.

The Manchester Corporation have asked the society to get an exhibition together in Queen's Park. This probably will be opened in Whit-week, and will form the first official recognition of photography as "an art" by the municipal authorities.

THE Morpeth Y.M.C.A. Camera Club's third exhibition was opened on May 14 in the lecture hall of the association. The judge was Mr. Charles F. Forster, F.R.P.S., Liverpool, and his awards were as follows:—

#### OPEN CLASSES.

Class A.—Bronze plaque, "The Deserted Mill," Harry Lindoe, Sunderland; bronze plaque, "A Lowland King," J. W. Whitehead, Alva, N.B.; bronze plaque, "The Solace of Old Age," O. C. Wilmot,

Sunderland; diploma, "Well Caught!" Alfred Taylor, Whalley; diploma, "Profile," Sydney H. Wood, Darlington; diploma, "Study of a Head," W. F. Holdsworth, Beckenham, Kent; diploma, "Departure of the Mauretania," W. Coats, Junr., Tynemouth.

Class D (Lantern Slides).—Bronze plaque, "Song Thrush," G. A. Booth, Preston; diploma, "Native Café, Tunis," Ald. G. B. Bainbridge, Espley Hall.

Class C (Federation Class).—Federation plaque, "To Wait an Answer," Easton Lee, Newcastle; bronze plaque, "Dawn," Harry Lindoe, Sunderland; diploma, "The Foy Boat," Harrôp P. Wight, Gosforth; diploma, "A Bit of Newlyn, Penzance," J. W. Gladson, Sunderland.

#### MEMBERS' CLASSES.

Class D.—Bronze plaque, "River Mists," Harry Dixon; diploma, "The Heights, Madeira," Ald. G. B. Bainbridge.

Class E.—Bronze plaque, "Puzzled," L. A. Loades; diploma, "Landing the Catch," J. T. Harrison.

Class F.—Bronze plaque, "Roses," L. A. Loades; diploma, "Flower Study," J. T. Harrison.

Championship (Members' Classes).—Harry Dixon.

Winner of Monthly Competition held during past session.—Harry Dixon.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been made between May 4 to May 9:—

MATERIAL.—No. 9,666. New or improved material or substance for photographic or like purposes. Ilford, Ltd., and Frank Forster Renwick, 8, Quality Court, Chancery Lane, London.

COLOUR SCREENS.—No. 9,693. Improvements in or relating to the manufacture of colour screens suitable for photographic and other purposes. George Sydney Whitfield, 46, Lincoln's Inn Fields, London.

CINEMATOGRAPHS.—No. 9,699. Improvements in apparatus for producing and displaying cinematographic photographs. Max Hansen, 256, Portland Street, South Norwood, London.

CINEMATOGRAPHS.—No. 9,711. Automatic light cut-offs for machines for projecting cinematographic pictures. Vincent Edward Horsman, "Cratfield," Grove Road, Wallasey, Cheshire.

CINEMATOGRAPHS.—No. 10,014. Improvements in mechanism employed in the production of cinematographic and microscopic pictures, and dark slide for carrying sensitive photographic plate for taking impressions. Henry William Hamblin Palmer, 43, St. Martin's Lane, Charing Cross, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

KITE CAMERAS.—No. 18,399. 1907. The invention consists of a photographic apparatus which can be let fall from a kite or other aerial support, and a photograph taken during the fall. The apparatus is thus free from the influence of the body from which it falls at the moment the exposure is made.

The apparatus is used in the following manner, it being assumed that the photograph is to be taken from a kite. To the kite is secured the holder 4, the levers of which engage under the handle plate 10, and thus connect the holder and the camera. By loosening the clamping nut 11 the handle can be moved in the slot and thereby the object glass is placed at any desired angle. The direction in which it is desired to photograph is fixed by turning the camera with the bottom portion of the handle in the union 12, and thereupon clamping it.

After the shutter mechanism of the camera has been cocked in well-known manner, the cord 3 is passed through the eye 14, connected to the shutter mechanism, thereupon the two parts of the casing 2 are closed, and the kite with the device suspended to it allowed to rise. The apparatus in that position is shown in the figure.

After the kite has reached the desired height a runner is up on the holding cord 15, and presses against the member 17. runner consists of a simple disc 16, which can be moved by the On the holding cord the member 17 connected to a locking mechanism is suitably secured, and against this member the runner 16 is pressed. Thus the locking device of any desired form is released, upon the plate 7 is drawn back by a spring arranged in the locking device.

When the length of cord 3, loosely arranged in the casing

extended and begins to move through the eye 14 the shutter is released and the plate is exposed during the free fall.

The oscillations or the movements of the kite cannot have any effect on the camera falling free in the vertical direction, that a sharp and clear picture is obtained.

The movement of the apparatus in the vertical direction the exposure of the photographic plate does not affect the picture taken if the exposures are sufficiently short. Georg Bruno, 32 Residenz Strasse, Strehlen, Dresden, Germany.

CINEMATOGRAPHS.—No. 14,493. 1907. The invention relates to the production of reduced cinematograph pictures by photographing the successive pictures of an ordinary cinematograph film through a microscope on to a sensitised plate or film, to which means are given such that the reduced series of pictures is produced in a spiral, or in spirals, or in a ring, or in concentric rings on the plate or film. Bessie Kate Brown and Theodore Brown, Villa Road, Brixton, London.

CINEMATOGRAPH-PHOTOGRAPH.—No. 9,391. 1907. The invention consists of a cinematograph film, which is adapted to be synchronous with a concordant record of sounds, provided with two photographic pictures, one of the sets representing place, events, characters, the deeds of said characters or suitable items of interest relating to a song, musical production, the like, and the other set representing the expressions, of a singer or other performers. George Robson, 21, Rochdale Road, Leyton, Essex.

#### New Trade Names.

VINDONISSA.—No. 300,336. Chemical substances and compounds used in photography and colours for typographic and lithographic impressions and impressions on metal, artists' colours, blacks, siccatives, or dryers, varnishes included in Class 1, like articles included in Class 1. Chemische Fabrik Brugg & Co., near Brugg Station, Brugg, Canton Aargau, Switzerland, manufacturers. February 10, 1908.

DEVICE.—TWO ROMAN SOLDIERS.—No. 300,337. Chemical substances and compositions used in photography, and colours for typographic

photographic impressions and impressions on metal, artists' lamp-blacks, siccatives, or dryers, varnishes included in and the like articles included in Class 1. Chemische Fabrik Actien-Gesellschaft, near Brugg Station, Brugg, Canton, Switzerland, manufacturers. February 10, 1908.

RED BALL BRAND).—No. 301,289. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives, but not including white lead and not including any of a like kind to white lead. Stevenson and Howell, Ltd., and Works, 95A, Southwark Street, London, manufacturing. March 13, 1908.

—No. 301,644. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives, but not including paints and not including any goods of a like kind to Devices, Ltd., 150, King's Cross Road, London, manufacturing. March 24, 1908.

—No. 302,189. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. The Nobles and Hoare, 3, Cornwall Road, Stamford Street, S.E., varnish and japan manufacturers. April 11, 1908.

—No. 302,190. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. The Nobles and Hoare, 3, Cornwall Road, Stamford Street, S.E., varnish and japan manufacturers. April 11, 1908.

—No. 302,192. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. St and Harding, Mansion House Chambers, 11, Queen Street, and Alpha Works, Millwall, London; and Phoenix and Temple Gate, Bristol, white lead, paint, colour and manufacturers. April 11, 1908.

—No. 301,509. Photographic cameras. Edward James Feilden, smont Road, Springfield Park, Acton, London, W., chief agent to a public company. March 19, 1908.

—No. 301,114. Photographic materials included in Class 39. Ltd., 56-61, Clerkenwell Road, London, E.C., dealers in photographic materials. March 7, 1908.

—No. 301,313. Pictures, photographs, and photo- mounts, made of paper or cardboard. Herbert Arthur son and Edward Rowlandson, trading as Hutchinson and son, 12, Phillimore Terrace, High Street, Kensington, W., photographers. March 13, 1908.

## Analecta.

*from our English weekly and monthly contemporaries.*

### An Autochrome Exhortation.

Photographers have been seeking (writes Mr. J. C. in "The Amateur Photographer and Photographic News") to eliminate the element of colour from their mental pictures, and to look upon nature as a colour-blind man would be looking for their pictorial results on fine composition, light and shade, and beauty of tone. The various photographic exhibitions all over the world testify to their success. By the indefatigable energy and genius of the Brothers Lumière photography has been enriched with a new and beautiful characteristic of which is the wonderful rendering of nature to which we have for so long turned a blind eye. The trouble is that in most cases photographers are unprepared to use the new and wonderful power. Those who have been most successful in eliminating colour from their consideration often know too well that it is now within their reach. The first of all photographers who were able to obtain Autochrome pictures have been to ransack larder and garden and the brightest and most varied coloured objects they could find. These, fearfully grouped upon a scarlet or bright cloth (with an actinometer hidden from view behind one corner), were tremblingly focussed and exposed till the actinometer told that they were properly cooked. May one who has suffered from blindness and monochromatic vision for many years, and whose colleagues in affliction the necessity of treading this new and brilliant path; remembering that harmony

is as important in colour as in tone, while a discord is more painful in the former case; that contrasts of colour are as valuable, in the right place, as contrasts of light and shade, and even more telling; and that finally, although in a colour picture scheme is the first essential, yet composition and light and shade have also to be considered.

### Drying Negatives.

Glass negatives may be dried quickly in two ways (says a writer in "Photography and Focus" for May 19)—by spirit or by heat. The negative should first be allowed to drain "surface dry," and its back and edges should be wiped quite dry. It is then placed in a dish and covered with methylated spirit. After remaining for three minutes in this, it is drained and transferred to a second bath of spirit for a couple of minutes, and then put up to dry in a warm place. It will stand more heat than if it were wet with water. In this case the drying is rather deceptive, and the negative may appear surface dry, yet still be sticky enough to adhere to the paper in the printing frame. It is well to let it have as long again to dry as it appears to take. One bath of spirit may be used, but in such a case the drying takes longer. The spirit may be kept for this particular purpose, and poured back in the bottle afterwards. In such a case, finely powdered plaster of Paris should be kept in the bottle, which should appear about a quarter full of the plaster, and when the spirit is poured back it should be well shaken up. The plaster extracts some of the water which the spirit has acquired from the negative. To dry negatives by heat, the film must first be made insoluble. To effect this, after the last washing it should be put in commercial formalin 1 oz., water 5 oz., for three minutes. It may then be momentarily rinsed under the tap and dried in front of the fire. A simple method of drying by heat is to place the negative, after the treatment with formalin, in a dish of boiling hot water for a minute, and then to put it in a current of air. The heat acquired from the water causes it to dry in a minute or two. These methods, however, never result in quite such good negatives as when the drying has taken place naturally.

## New Books.

"Die Milchstrasse." By Professor Dr. Max Wolf. Leipsic: Johann Ambrosius Barth. Price 4 marks.

Professor Max Wolf has produced an attractive volume in which is given a short description of the Milky Way. It is illustrated by a series of beautiful photographs taken at the Heidelberg Observatory with a wide-angle lens. These are presented in ten plates, showing the most prominent regions of the galaxy, all taken with a small lens with a large field, thus giving more close approximation to what is seen with the unaided eye than the usual large scale photographs. The short discussion of the various theories of the construction of the stellar universe is illustrated by photographs of the more prominent spiral nebulae, and large scale pictures of a few of the richest regions.

"The Nature Book." Part I, May 23, 7d. nett. Cassell and Co., La Belle Sauvage, London, E.C.

This is the first part of a new publication that is to be completed in twenty-four fortnightly parts, and, from this first number we should judge that it will be a work highly appreciated by photographers. It is devoted, as its title indicates, to Nature study and is well illustrated with photographs and reproductions of water-colour drawings. The quality of the illustrations can be judged by the fact that among the numerous contributors are Messrs. Douglas English, Martin Duncan, Richard and Cherry Kearton, Walter Crane, J. Lomas, Henry Irving, and J. J. Ward. The paper used is of good quality and the reproductions therefore show up excellently. The present number contains an introduction by Walter Crane, and the first parts of articles on "How to Know the Wild Animals," "How to Know the Clouds," "How to Know the Wild Flowers," "How to Know the Birds," and "How to Know the Trees Growing in Great Britain." This list of titles fairly well shows the field that the book will cover, and when we realise that each of these subjects is illustrated in a detailed fashion that is quite unfamiliar in the ordinary Natural History book the value of the work, as a whole,

can be appreciated. Mr. Henry Irving's photographs of wild flowers are worth special mention, as examples of what such illustrations should be. The full page illustrations include a fine example of Cherry Kearton's work and a reproduction of a water-colour drawing by Mrs. Allingham.

"Annuaire Général et International de la Photographie." Plon, Nourrit and Cie., Paris, 1908, 6 francs net.

This is the 17th year of this annual, and this volume is conducted on the same lines as previous issues. As usual, it treats the reader to a hors-d'œuvre in the form of a comedy in one act before proceeding to the more serious task of reviewing the year's work in photography. Numerous tables, recipes, and formulæ are collected together in the third part of the book, and though the information concerning English societies and publications is by no means up-to-date, the annual, as a whole, is a useful and excellently got-up work of reference.

"The Photo Miniature," Nos. 87 and 88. Tennant and Ward, New York, and Dawbarn and Ward, London.

The March number of "The Photo Miniature," No. 87, is devoted to "Bromide Enlarging Made Easy," and it treats the subject in very clear and lucid fashion, covering the ground very completely in a small number of pages. Numerous useful tables are given, and this number of the Miniature should be a very useful one to many photographers. The April number of the Miniature is No. 88, and this treats upon "Defective Negatives, with Practical Remedies." This is not simply a book on intensification and reduction, as its title might seem to imply, but one treating of a number of familiar troubles due to sundry causes, such as drying marks, developer stains, stains from packing and sundry chemicals. Scratches, cracks, etc., are also dealt with, and altogether the book is one of a rather novel and very useful kind.

"Handbuch der Praktischen Kinematographie," von F. Paul Liesegang. Liesegang's Verlag, Leipzig, 8vo, 302 pp., 125 illus. 8 marks, bd. 9 marks.

The work before us is—an eminently practical one, intended mainly for the instruction of operators of exhibition machines. The subject is very clearly explained, as might be expected from an author of Herr Liesegang's repute, and a very good outline of the general mechanical details of typical present-day machines is given with impartial consideration, the Liesegang machines receiving no undue prominence. The book is written on special lines; no historical matter is included, nor is any account of the various uses of the cinematograph given. The space thus saved is devoted to a description of the optical system, including variable focus lenses, and to a sixty-page account of all practical methods of lighting, both these subjects being treated from the users' point of view rather than from a theoretical one. The taking of negatives, the making of positives and the care of films, all find a place, while the chapter on flicker and its relation to shutter-aperture and brilliancy of light is written in a very practical way. The book, indeed, is not intended for the constructor or inventor, but rather to give that general information respecting the actual working of commercial machines and how to get the best out of them which has hitherto only been transmitted by word of mouth to purchaser or operator. Indeed, the work might well have borne the sub-title "The Cinematograph Operator's Handbook," and we believe it to be the first German work of that type.

**A PHOTOGRAPHIC RECORD BOOK.**—At a meeting of the Colwyn Bay Town Improvement Association, held on the 14th inst., it was decided to establish and preserve at the Town Hall a photographic record book. The idea is to procure not merely photographs of the many picturesque spots in the district, but photographs showing the development of the town at various times, interesting public functions, old buildings and improvements, all kinds of photographs, in fact, which will in the future have any historical interest. Amateur photographers who have prints of local interest are invited to contribute to the portfolio. The name of the donor will be recorded under each print if desired, together with requisite particulars. Prints should be sent to The Secretary, Town Improvement Association, Town Hall, Colwyn Bay.

## New Apparatus, &c.

**SILVERINE FRAMES.**—Messrs. John J. Griffin and Sons, Ltd., send us a specimen of their "Silverine" frames, which have the effect of finely frosted silver. They are decorated with

relief, and are specially recommended for dark black-and-white sepia prints. The sizes and prices are as follows: Midget, C.D.V. or  $\frac{1}{4}$ -plate, 9d.; cabinet or  $\frac{1}{2}$ -plate, 1s. 1d. The frame obtainable with the opening oval, round, or rectangular.

## New Materials, &c.

The New Watkins' Speed List: Watkins Meter Company, Hertford.

We have received a copy of the new speed card referred to in "Analecta" last week. This differs from the old list in that the development speed is given as well as the exposure speed. Development speed is denoted by letters, which signify a number of minutes' development at 60deg. F., according to the following table:—

Development Speeds.					
V.Q.	Q.	M.Q.	M.	M.S.	S. V.S.
$\frac{1}{2}$	$\frac{2}{3}$	$\frac{3}{4}$	$\frac{4}{5}$	$\frac{5}{7}$	$\frac{7}{11}$

These times are intended to apply to the special Watkins developer, which will shortly be issued. A novelty is proposed in the form of a thermo-indicator attached to the bottle, so that changes can be made for the actual temperature of the workroom. It is pointed out that, while other developers will require different development times, yet the ratio between the different groups of plates will remain the same, so that the table of speeds is useful in all cases, whether the special developer is used or not. There is no doubt that a system of development, based on temperature, is the most satisfactory in use, and Mr. Watkins' system will no doubt speedily prove its value.

**The Castell Pencil.** A. W. Faber, 149, Queen Victoria Street, London, E.C.

Mr. A. W. Faber submits to us a sample of a new "Castell" pencil of very high quality. The Castell pencils are supplied each, or 3s. 6d. per dozen, and, having had the opportunity of using them for some little time, we can fully confirm the manufacturer's statements as to quality, durability, and smoothness of work. Probably some of the harder grades will be of great service in retouching. It can be obtained in sixteen grades, from 6B to Nos. 7 and 8H are intended for lithographic work on stone.

**Illingworth's Cream Crayon Smooth Bromide Paper.** T. Illingworth and Co., Willesden Junction, London, N.W.

Messrs. Illingworth have introduced a new brand of their bromide paper, which is likely to be appreciated. It has a very pleasant "natural" surface, not dead smooth, and has only just sufficient gloss to obviate the dull matt effect generally given by such papers. The paper is rapid, and yields excellent blacks, and in our own tests we can recommend it to the attention of those who like a surface that is neither matt nor yet glossy.

# CATALOGUES AND TRADE NOTICES.

**THE PRISM.**—The current issue of this beautiful miniature album contains an article on "Flower Portraits." "The Prism" is obtainable from Messrs. A. E. Staley and Co. for 1d.

**PHOTOGRAPHIC MATERIALS.**—Mr. E. J. Thom, of 63, St. Paul's Churchyard, London, E.C., has issued a list of the various photographic materials which he is in a position to supply, amongst which are a large variety of printing papers, mounts, backgrounds, and other accessories. In fact, most photographic requisites from printing machines, blocking, and stamping presses, etc., down to small articles as postal wrappers may be obtained from Mr. Thom at the above address, who will supply full particulars as to prices, etc., upon application.

**CITY SALE AND EXCHANGE,** of 54, Lime Street, London, E.C., has issued a copy of their latest list of second-hand photographic apparatus. The list includes particulars of a large variety of hand cameras and lenses, which are offered at considerably reduced prices, and include goods by most of the well-known makers. A copy of the list, which is well worth perusal, will be sent free on application to the above address, the firm also stating that other apparatus will be taken in whole or part exchange for any article selected from their list.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, MAY 23.

**Middlesex Photographic Society.** Outing to Ayot (combined outing of affiliated Societies).  
**Camera Club.** Excursion to Hull.  
**London Photographic Society.** Affiliated Societies' outing to Ayot, near field.  
**North Photographic Society.** Affiliated Societies' outing to Ayot, near field.  
**Photographic Society.** Excursion to Claygate.  
**Stereoscopic Society.** Outing to Wake Valley.  
**Urban Photographic Society.** Affiliated Societies' Outing to Ayot, near field.  
**Photographic Society.** Excursion to Bilton, Dunchurch, and Thurlaston.  
**Photo Art Club.** Excursion to Fetteresso.

MONDAY, MAY 25.

**London and District Photographic Society.** "Time Development." W. F. E. R.  
**London Camera Club.** "Stereoscopic Photography." W. H. Trigg.

TUESDAY, MAY 26.

**Photographic Society.** "A New Method of Securing Uniformity in Bromide Printing." Thomas Manly.  
**Photographic Society.** "Trimming and Mounting." A. J. Linford.

WEDNESDAY, MAY 27.

**Technical College Photographic Society.** "The History of Colour Photography." R. C. Gale.  
**Camera Club.** Portfolio Evening.  
**Middlesex Photographic Society.** "Gum Bichromate." C. Wille.  
**Urban Photographic Society.** "Pictures from Holland." Stanley E. Ham.

THURSDAY, MAY 28.

**North Photographic Society.** "Bromide Printing and Toning." E. G. R.  
**London and District Camera Club.** Members' Evening.  
**London and Provincial Photographic Association.** "Sinop Demonstration." Yerbury.

### ROYAL PHOTOGRAPHIC SOCIETY.

General meeting on Tuesday, with the president in the chair, Mr. H. Oakden gave an extremely interesting lecture on architecture in Ireland. He began by a historical—or, rather, pre-historical—survey of the subject, and showed a fine set of slides illustrating the national architecture from the most primitive cromlech-houses, tumuli, and round towers up to quite modern buildings. The audience showed a marked appreciation of the lecture, which was quite a valuable one from an archaeological and historical point of view.

**LONDON CAMERA CLUB.**—Mr. W. F. Slater, F.R.P.S., representing the Kodak Co., Ltd., read a paper last week on "The Theory and Practice of Time Development," having particular reference to the new and highly ingenious Kodak tank. An unusually large number of members attended. It is not too much to say that the tank was a model of lucidity and arrangement, and must have

afforded the beginners a valuable lesson, a series of glorified kindergarten models materially assisting towards a comprehension of the principles underlying the subject chosen.

A very strong case was made out for "time development for a fixed period," and had Mr. Slater contented himself with claiming that the Kodak system was capable of producing a far greater percentage of good results than those obtainable by the ocular method all present would have cordially agreed with him, so far as the system was applicable to the less advanced worker, and would probably have admitted, as quite open to argument, that the expert on an average might equally benefit by adopting it. The lecturer, however, went very much further than this, and in effect undoubtedly contended that development for a fixed period was capable of doing, in every case and under all conditions, everything that variations of time or modifications of the developer could achieve. Highly controversial points were raised at every turn and dealt with summarily, and even dogmatically, in favour of the system advocated. A comparison was also drawn between films and plates as regards relative cost and time of working, which by no means found acceptance. It would perhaps not be fair to give the entire purport of the animated and incisive discussion which followed, because at its close there was insufficient time to enable Mr. Slater to reply fully; indeed, he said, it would take an entire evening to do so. It would be equally unfair not to mention that one and all congratulated him on his lecture, although a general opinion was expressed that he had seriously weakened an excellent case by overstating it. Mr. E. A. Salt tried in vain to get the lecturer either to admit or deny the influence of a bromided developer, applied, in the first instance, in cases of known over-exposure. Dr. Mees pointed out that the work of Messrs. Hurter and Driffield, Mr. Watkins, and Dr. Sheppard and himself, was based on the assumption of correct exposure. Very few negatives in their entirety were, he stated, in this region. Messrs. Hurter and Driffield, in their second paper, had dealt with a bromided developer, which was most useful in cases of known over-exposure. Rules for under-exposure were complicated. For most snapshots one rule generally held—viz., "pushing development was equivalent to exposure." On the other hand, if portions of the negative had been correctly or fully exposed then, of course, prolonging development would make such parts too dense. He had shown years ago, at the Croydon Camera Club, that if two plates were taken, one fast and one slow, and an exposure given, under-timed for the fast plate, and also assuming the whole plate to be under-exposed, then the capability of the slow plate to stand forcing in development would more than compensate for the extra speed of the other. In reference to Mr. Slater's remarks as to the time taken to develop plates, a friend of his had exposed five gross during a recent trip on the Continent. According to the lecturer, their development should have occupied 150 hours. It did not. The president (Mr. J. M. Sellers) said that the Kodak system made no allowance for variation of subject; in strictness different sorts of subjects required varied periods of development. Mr. F. W. Hicks agreed. Snapshots on the sea and in the streets would certainly require different times. Mr. H. P. C. Harpur showed a satisfactory picture from a negative which necessarily had to be grossly under-exposed. It had been developed for three-quarters of a minute. Temperature of developer 80 deg. Fahr. Mr. W. H. Smith said that if two negatives were taken, having the same relative contrasts, but one very dense, the other of normal density, they would not give similar prints, in one process at least (presumably platinum-type). With the former the light might have just sufficient power to get through the most opaque portions, but the darkening of the paper underneath seemed to arrest further light action.

During the evening Mr. Long handed round a most successful autochrome of a group of flowers, which seemed to lack nothing in brilliancy or truth of colour rendering. When exposed the plate was over ten months old.

**THE AFFILIATION.**—At a meeting of the Executive Committee, held on Friday evening last, the resignation of Mr. Sterry from the position of treasurer, an office he has held for many years, was received with great regret, and Mr. Leslie E. Clift was appointed treasurer pro tem. The vacancy thus caused on the committee was filled by the appointment of Mr. C. Churchill (Woolwich P.S.).

The acting secretary reported that the Red Books were now in the hands of the affiliated societies. A vote of thanks was accorded

Dr. Evershed for the work he had undertaken in editing the Red Book this year, and it is hoped the value of the new edition will be duly appreciated. Several new lectures of considerable interest will be shortly ready for circulation.

The half-yearly meeting of the delegates will be held on Wednesday, June 17, at 6.30 p.m.

It was reported that the arrangements in connection with the outing to Ayot on May 23 were now quite complete, and an enjoyable day was anticipated.

**LONGRIDGE CAMERA CLUB.**—The following officers have been appointed:—President, Rev. R. W. Berry, A.T.S.; vice-president, Mr. J. Monk; secretary, Mr. J. Robinson; treasurer, Mr. H. Cross; auditor, Mr. Marshall; committee, Messrs. Dewhurst, Marsh, Crook, and the officers ex officio. The subscription has been fixed at 5s. per year.

**BEDFORD CAMERA CLUB.**—The third annual meeting was held at Deacon's Rooms. The Secretary reported that the membership is rapidly increasing, and that he held a substantial cash balance, although expensive fixtures had been purchased during the year. Mr. F. H. Langdon-Davies, a member thoroughly acquainted with the technical and pictorial sides of photography, was unanimously elected president, Mr. W. Deane, Mr. B. Schon, Dr. Willmer Phillips, Dr. Harvey Goldsmith and Dr. J. E. Morris were made vice-presidents, Mr. W. D. Simpson, hon. sec. and treasurer, and Mr. W. Norman Blake, hon. lanternist were re-appointed, and the following were chosen as the committee: Messrs. C. P. Anthony, J. Beanland, H. B. Wells, J. Shepherd-Smith, Charles E. Craddock, E. F. Buttfeld, W. H. Hodge, H. S. Brawn, G. Cocking and E. T. Fell. A new and important feature will be introduced into the club's programme for the coming season solely for the benefit of novices in the form of lectures by leading members, dealing with such subjects of elementary photography as exposure, development, printing, toning, enlarging, etc., and lasting from 7.45 to 8.15, when the ordinary meetings will commence. This will enable beginners to gain a knowledge of the groundwork of this interesting hobby. The first meeting of the new year will take place on Monday, May 25, when enlarging will be demonstrated. A local competition for prints will be held in the autumn, and the exhibition proper will take place early in 1909.

## Commercial & Legal Intelligence.

**ENLARGING FEES.**—Mr. A. S. Davis, 134, Cheapside, claimed £9, the balance of £11, for two photographic enlargements executed for Mr. Bhumgara, 135, London Wall. Mr. Croon Johnson, plaintiff's solicitor, said that the price was agreed at £5 10s. each, and the defendant paid £2 on account. Now the defendant said he wanted the photographs enlarged on the platinotype basis, but that was not stipulated until after the order was booked. Defendant said there was no doubt that the order was for the photographs to be enlarged in platinotype. Plaintiff said he was still willing to do them in platinotype. The Judge thought that was the best way out of the difficulty. Plaintiff, he added, would pay the defendant's costs.

**THE FREE PHOTOGRAPH BUSINESS.**—Mrs. Agnes M. Ball, of Hawes Road, Bromley, sued J. Misener, whose address was given as "The Studio," 17, Lewisham High Road, to recover 17s. 6d. Plaintiff said that defendant's representative called on her and said they were starting a business in Bromley, and with a view to advertising themselves he would give her a free enlargement of any photograph she liked to produce. After a certain amount of talk she gave him a photograph to be enlarged. It was very much against her will, but the man said it would be so kind of her to do it to assist him. After she had consented to have the free photograph the man said: "I suppose if you get a photo you will give us the order for a frame?" and witness said "Yes." Subsequently someone else called from the defendant and showed her a proof of the enlarged photo, with which witness was quite satisfied, and then he proceeded to speak about the frame, which, he said, would cost 16s. Witness said she was not accustomed to pay so much for a frame, and he said he would make it for 14s., and it would be of

English oak, English gold, and plate glass. She was induced to give the order on the faith of that representation; more so she wanted to get rid of the man. George William Earle, a photographer, said the frame in question was only common deal. It was exactly the same thing in stock, and he produced a specimen frame supplied by the defendant would cost 3s. 6d. It was of English gold, and the glass used was of the ordinary common type would not cost more than 4d. The outside value of the frame and glass complete would be 3s. 6d. His Honour said it was unwise on the part of people to encourage these men by giving orders. He was told this was somewhat of a test case for the protection of the public. He could hardly believe that there were many innocent people about who believed that a photograph could be presented to them free of charge, but it appeared that the plaintiff did believe it, and so he assumed that other people would do so. Plaintiff had made out her case. The idea in this case was to get an exorbitant price for the frame. Judgment was given for plaintiff for 17s. 6d. (14s. for the frame and 3s. 6d. carriage) and costs.

**RECEIVING ORDER.**—A receiving order has been made against Ralph Winter Thomas (trading as the Western Camera Company) residing at 28, Burghley Road, St. Andrew's Park, Bristol, carrying on business at 69, Stokes Croft, Bristol, as a photographic dealer.

**DIVIDEND.**—A dividend is to be paid in the bankruptcy of Percy John Swain, photographer, of 37, Earlam Road, Norwich, carrying on business under the style of John Percy at 2A, Place, Norwich. Claims should be sent by May 30 to the Receiver, 8, King Street, Norwich.

## News and Notes.

**PHOTOGRAPHY AT THE ROYAL INSTITUTION.**—The syllabus of Alexander Scott's lectures to be given on May 28 and June 4 at the theatre of the Royal Institution, Albemarle Street, is as follows:

May 21.—The chemical and physical actions of light on elements and compounds—Application of these actions to the measurement of the quantity, the quality, and the intensity of light—The spectrum and its chemically active rays—Definition of rays—Effects produced by different colours—Early attempts to produce chemical changes so as to reproduce pictures—Experiments of Wedgwood, Herschel—The photographic processes of Nicéphore Niépce, Daguerre, and Fox Talbot—The chemistry of the salts of iron, chromium, etc., with especial reference to the photographic processes of the present day.

May 28.—The Daguerreotype, the wet and dry collodion, compared with the gelatino-bromide plate—Negatives and positives—The nature of the latent image—Development of the latent image—Sensitising agents—Solarisation and reversal of the image—The image—Intensification and reduction—Theory and practice of silver, platinum, carbon, and gum-bichromate processes for producing positive pictures.

June 4.—The action of dyes on a gelatino-bromide plate and iso-chromatic plates—The rendering of various colours in tone—Can coloured objects be represented in their true colours by purely photographic methods?—Processes of colour photography—Lippman, Sanger Shepherd, Lumière, and others—Production of pictures on the photographic plate by agencies other than light.

**THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Ernest Human, the hon. sec., asks us to say that owing to the proprietorship at the Olde Napier Tavern, it has been found necessary for the comfort of the members to obtain new meeting rooms. The meetings will for this reason be held, on and after Tuesday, May 21, at "The Apple Tree and Mitre," 30, Cursitor Chancery Lane. The new rooms are only two minutes' walk from Chancery Lane tube station, and are easy of access from all parts of London. On Thursday, May 28, a demonstration of the new process is to be given by Mr. S. G. Yerbury, and visitors are offered welcome to this, as they are to any of the meetings of the Association.

## Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

### SUNDAY LABOUR.

To the Editors.

Gentlemen,—I venture to write you on a subject which appeals much to a certain class of workers in photography, viz., the vast amount of Sunday labour. Leaving the subject alone from religious point of view, Sunday labour in any form, unless absolutely necessary, is a blot on our national civilisation, and ought to be rigidly suppressed by law. There is, I believe, a very old law against this violation of the Sabbath, making such an offence punishable by a fine, but I have never heard of a photographer being proceeded against. We managers and operators work long enough during the six days, usually from nine till eight, to deserve the Sabbath ourselves. Then, I ask, what are we paid for Sunday labour? Or do we get in return for having our Sunday broken into?—thus preventing us from seeking a change of scenery. We get the so-called half-day, which usually means closing at four or five instead of eight o'clock, and our Sunday duty may be anything from four to eight hours. As a broad-minded Englishman, I do not blame any man for making as much as he can by fair means. What I propose is: If a photographer feels it is necessary to open his studio on Sunday, he should be prepared to do the operating himself, and not employ an assistant of his hard-earned rest. If all photographers complied in each town and refused Sunday work, unless in an exceptional instance, Sunday patrons would soon find time to do their own best on their early-closing day, and no one would be the wiser. I wonder how many football enthusiasts there were who missed seeing the recent English Cup Final? I repeat, the law ought to step in and stop Sunday trading by a fine for the first three offences, and for the fourth, which I may call imprisonment without the option of a fine would be a penalty.

SIX DAYS.

### RETOUCHING MEDIUM.

To the Editors.

Gentlemen,—I have pleasure in introducing to readers of the "B.J." a somewhat original formula for retouching medium which dries very rapidly, with a smooth hard surface, giving an excellent finish to the pencil. As my business is connected largely with photography and varnishes, I have made several experiments, eventually arriving at the following:—

Pure American turpentine .....	1½ ozs.
Oil of spike .....	½ oz.
Male resin .....	1 oz.
Raw linseed oil .....	8 min.
Serebene .....	20 min.
Essence of pear .....	½ oz.

The two latter are used for their quick drying propensities. If the medium is too thick, it may be diluted with more turpentine. Only the smallest possible amount is required to be spread over the negative, and those parts to be retouched, and it is best applied with the finger.

Yours faithfully,  
A. T. HALL.

### PUTTY FOR GLAZING STUDIOS.

To the Editors.

Gentlemen,—I am sure "Nero" will find what he inquires about in your week's issue of the "B.J.," a putty that does not dry hard, and is written by W. Carson and Sons, Grove Works, Battersea.—Yours faithfully,  
JOHN TERRAS.

To the Editors.

Gentlemen,—I notice in to-day's "B.J." a query as to "Putty for glazing Studios." This probably refers to a letter of mine on the subject, in which I told you that I had had my greenhouse reglazed by W. Carson's Plastine. I may tell you that my greenhouse is still perfectly sound.—Yours faithfully,  
J. E. GUBBINS.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- A. Ridley, High Street, Tenterden, Kent. Photograph of the National Sanatorium, Benenden, Kent.
- C. Spence, The Studio, Station Road, Dunbar. Photograph of a Ship Tossed on the Rocks, called "After the Storm near Dunbar."
- E. McGeachie, Studio, Pier Road, Dunoon, N.B. Photograph. Dunoon Grammar School Continuation Class, 1908. "Faust."
- W. H. Hutchings, Vine Villa, Hepburn Road, Stokes Croft, Bristol. Photograph of Fred Archer, John Porter, and Racehorse, Ormonde.
- E. Clapham, 30, Byrom Street, Todmorden. Photograph of John Wm. Crabtree, Captain of First Team, Todmorden Cricket Club.
- J. MacLachlan, 23, Stewarton Street, Wishaw. Photograph of the Rev. W. Stott.

**COPYRIGHT.**—With reference to a question of ours re copyright you were good enough to answer in the issue of February 21, we beg to mention that our firm was not paid in the first instance for taking the photograph. We at a subsequent date, however, supplied the gentleman who granted permission with several copies (to order), and for which he paid at the same rate as the public—i.e., any other customer. The present owner's agent annoys us by questioning our right, and asserting that the permission of thirty years ago could only be valid during the lifetime of the owner who granted it. We certainly object to surrender our rights, and are anxious to be sure of our ground. Your reply will be esteemed.—  
MCISLE.

The copyright, being yours to begin with, cannot become somebody else's through the death of the sitter. There is nothing in the Copyright Act to suggest such a thing. You had better point out to the agent that copyright lasts for the life of the "author," and seven years after his death, the author in this case being the one who photographed the deceased gentleman.

**FABRIC.**—The most practical process is platinum or kallitype, as directed in the current "Almanac." The chief point is the thorough sizing of the fabric, preferably with arrowroot. We advise you to get Duchochois' book, "Photographic Reproduction Processes," published by Hampton and Co., 12, Cursitor Street, E.C. (2s. 6d.).

**THE COPYRIGHT UNION.**—Kindly inform us through your valued journal if the Photographic Copyright Union still exists, as we have not heard of it for some time.—  
LLEWYLLA.

The Union is still in existence. Address the Secretary (Mr. H. Gower), at 22 and 23, Soho Square, London, W.

**WALES.**—It varies within wide limits. You cannot obtain a better idea than from the small advertisements in each issue of the "B.J."

**LENS FOR GROUP.**—I wish to photograph a group, about 800 in number, in a large hall (daylight). Could you kindly inform me which lens would be the best for taking the above, say, on a 15 by 12 plate, to cover well, without stopping down to any great extent?—  
OSBORNE.

We do not see that you can do better than employ a R.R., or a lens of the anastigmat type of about twenty inches focus. If the

hall is not long enough to permit of a lens of so long a focus being used, you will have to get a shorter one. Then an anastigmat will be the best, as it has great covering power in proportion to its focal length.

**COPYRIGHT.**—At an agricultural exhibition just held in this district we were granted the sole right of photographing in the showyard by paying a royalty. The day previous to the opening another firm came into the yard and took a photograph of a stand to the order of the manager of same. Not being acquainted with the law on this matter, we should be glad to know if we can do anything in the matter, either with the photographer or the secretary. Also, can we claim anything from the journals publishing photographs taken by their representatives with hand-cameras? We should be glad of a reply.—*SUSSEX.*

So far as we understand, the photograph was not taken to the order of any of the show authorities, but to that of one of the exhibitors. If you were there at the time the picture was taken, you should have prevented it, by appealing to those with whom you arranged for the sole right. We do not see that you can do anything in the matter now, beyond trying to get the show people to throw off some of the fee you are to pay—for any damage you may have sustained. You can do nothing with regard to the photographer, or the journals that may make use of the photographs.

**CAMPO.**—According to your statement, the people have slightly departed from the agreement, but we do not see that you have sustained any injury thereby, or such as you could recover damages for, particularly as there is no copyright in the pictures.

**FOG CAUSED BY DARK SLIDE.**—I am forwarding for your inspection a plate which, previous to development, had been left in a dark slide for about a fortnight. I should be much obliged if you could give any explanation of the general fog, and suggest any remedies. The plate was probably in a fresh condition. The slide was loaded, and the plate developed (pyro-soda Ilford formula) in complete darkness. The slide, which, as far as I can determine, is completely light-tight, is of metal, and has an aluminium shutter. Any suggestions you can make will be much appreciated.—*ERN. A. LYNN.*

A fortnight in a dark slide will fog most plates. Probably in your case the aluminium shutter helped in the fogging action and caused the spots.

**PZZLED.**—You can obtain elementary general text-books on photography at any booksellers, or write to Hazell, Watson, and Viney, or to Dawbarn and Ward, for a list of the books they publish.

**IGNITING FLASH POWDER.**—We should esteem it a favour if you would kindly inform us the best and simplest means of igniting flash powder by electricity, either from the direct current or from an accumulator. Full particulars will oblige.—*FLASHER.*

Put a short piece of very fine platinum wire in the circuit and bury the wire in the flash powder. A very small battery will be sufficient. See page 377 in our issue of May 15.

**COPYRIGHT QUERIES.**—A man asked me how much I would take a dozen views and do a finished silver print from each for, him to take the risk how many were good, so that he could copyright them if he wanted to or not, and also that I should not use the negative for anything else. I told him by word of mouth only 15s. per dozen. Now I have done the work and supplied the prints and he has paid me. Now, the thing I want to know is: 1. Who holds possession of the negatives if he copyrights the prints? 2. Who holds possession of negatives if he does not copyright the prints? 3. Can he demand the negatives in any way to give work to anybody else to do from them, or do I keep them myself? 4. If he did not copyright them should I be allowed to use them in any way or sell them?—*GEORGE CHAPMAN.*

In reply, 1. You do; the negatives are the photographer's property unless there is a special agreement that they are to be given up. 2. Whether the pictures are copyrighted or not makes no difference. 3. He can, of course, "demand" them if he likes, but he cannot enforce the demand. 4. Certainly not. You have

been paid for the work you have done, and there is at the end of the matter so far as you are concerned. You have no whatever to use the negatives for any purposes of your own, if the pictures are not made copyright.

**T. W. DIEBLE.**—If you agreed, when accepting the engagement, to work seven days a week the week ends on Sunday night. I absented yourself from work for two days, the pay for two days can be legally deducted. If you give notice to the notice should expire at the week end, namely, on the Sunday night. Practically, according to your statement, you did commence work till Monday morning, so that your week ends on the Sunday.

**LENS QUERIES.**—I shall be much obliged if you would kindly answer the enclosed queries in your next issue. I use a set of "Vademecum" lenses (card enclosed) but have some difficulty in regard to portrait subjects, and would ask for information on the following points: (1.) Do you advise a single lens for portrait work? (2.) If so, of what focal length when using a half camera for (a) head and shoulders, (b) three-quarter length, (c) full length, (d) groups; (3.) Would one lens do for all above? (4.) If a doublet should be used kindly say what combination.—*EDWARD R. PLOWMAN.*

1. A single lens may be used for portraiture, but, to obtain a sufficiently good definition for this class of work, it will require considerable stopping down, when it will be slow in action. 2. (a, b, c, d) One of about twelve or fourteen inches focus will give a pleasing perspective. 3. Yes, if the studio is long enough to enable the groups to be taken in it. If not one of shorter focal length must be employed. 4. Either the 75 and 65, or for groups 65 and 55.

**REDUCTION OF OVER-INTENSIFICATION.**—I recently over-intensified a negative by the bichromate method and should be greatly obliged if you could tell me the best method of correcting the fault. The actual formula used was:—

Potass bichromate .....	100 gr.
Water .....	10 oz.
Hydrochloric acid .....	50 mins.

and the redeveloper used was amidol.—*OPERATOR.*

Bleach again in:

Potash bichromate .....	10 gr.
Water .....	1 oz.
Hydrochloric acid .....	40 mins.

Let the bleaching solution act very thoroughly, and then soak in a 10 per cent. solution of potash metabisulphite until image nearly white. Then redevelop. You can use 5 per cent. hydrochloric or sulphuric acid in place of the metabisulphite if preferred. These acid solutions all act very slowly, and the process cannot be hurried.

**X. Y. Z.**—From what you say the prints are probably not permanent, and may go off in a month or two. We advise you to use the combined baths, as given in the "Almanac," p. 818. We are sorry that the answer to your query was crowded out of last week's issue.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received for the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Exhibition of the Society of Colour Photographers opens on Friday next at the house of the "British Journal." This exhibition will be open daily from 10 a.m. to 8 p.m. (Saturdays 10 to 5), charge of sixpence admission will be made.

D. J. Howell, in the concluding portion of his article on "As a field for photographers," discusses the qualifications which should be possessed by a photographer going to that country and gives some timely advice on living and clothing and the value of an outfit. (P. 411.)

Watkins has placed on the market a ready-made single-plate developer, together with data which permit the user to alter the peculiarities of commercial plates and the temperature developer when working by time. (P. 413.)

Draw attention in an editorial to the practical arguments for and against the time system of development. (P. 410.)

Lumière and Seyewetz, as the result of experiments on the use of dry plates with a mixture of ammonium chloride and hyposulphite, have come to the conclusion that though fixing is made more quickly, there is greater danger of unstable combinations being formed. (P. 417.)

American contemporary, in an article intended for photographers, draws attention to the profitable use to be made of printed postcards by photographers. (P. 419.)

German experimenters have recorded the results of subjecting plates to the action of potassium salts. (P. 420.)

Give the results of recent experiments by Drs. Stenger and others on the colour-sensitising of collodion emulsion. (P. 418.)

Mainly demonstrated his modified method of ozobrome at the meeting on Tuesday evening last. (P. 425.)

First of three lectures on the chemistry of photography was given at the Royal Institution on Thursday of last week by Dr. J. H. Scott. (P. 421.)

Among the patents of the week are an automatic folding camera, a reflex camera, and a collapsible lens-hood. (P. 422.)

## EX CATHEDRA.

### The Colour Photography Exhibition.

On Monday next, June 1, the exhibition of the Society of Colour Photographers will open at the offices of "The British Journal of Photography," and will remain open until Saturday, June 27. The exhibition, it will be found, demonstrates the continued progress being made in photographic methods of three-colour printing. Of particular interest are the prints by the pinatype process from Autochrome originals sent by M. Didier. These are the first results on paper from Autochromes to be publicly exhibited. The Transparency section includes a great deal of new work by the Autochrome process. The fruit and flower studies, which formed much of the first work on Autochrome plates to be exhibited, have largely given place to results showing what can be done in landscape and portrait colour photography. Herr Dührkoop sends some examples of his Autochrome portraits, and there are also a number by M. Meys, one of the notable French workers. This year the Society have decided:—

1. To keep the exhibition open from 10 a.m. to 8 p.m. (Saturdays, 10 to 5).
2. To charge sixpence for admission.

These changes will thus allow many who cannot get to the exhibition during business hours to visit the collection which has been brought together.

\* \* \*

**The Trimming** In the "B.J." ALMANAC for 1908, of **Stereo-scopical Prints**, amongst the rules for mounting stereoscopic prints on page 951, we give the following:—"Trim so that the separation of corresponding margins is only just less than that between images of nearest objects." A correspondent has noted that many fail to observe this rule and yet get apparently good results, and he therefore asks what is the object of the rule. There are occasions on which we can not only neglect the rule with impunity, but even obtain a better effect by so doing. These occasions are, however, rare, and in the great majority of cases the rule should be observed. If neglected the effects may not be noticed by the observer who does not understand the object of the rule, but they will be strikingly obvious to any one who knows that they may exist, and therefore looks for them. The reason of the rule is very simple. The nearer two corresponding points are to each other the nearer does their combined image appear to be to the observer. The margins of the prints have to be combined as well as the objects represented on the prints themselves, therefore if the smallest separation is kept between the margins the whole of the subject will appear to be behind the mount. In other words, the effect will be that of looking at the object through a rectangular opening or window in the mount.

When we fail to observe the rule, then some part of the subject will appear to stand out in front of the mount. If this is a part of the subject that is more or less central, or, at any rate, not near the margins, the effect may be good. We have seen slides trimmed in this fashion that were very striking. One was a mounted stag's head trophy, and the other a full face portrait of a tiger. In these two cases the animal's head appeared to project through the opening in the mount, and an almost startlingly realistic effect was produced. Suppose, however, the subject to be an erect human figure. If the trimming causes this to apparently stand out in front of the mount, then where the figure adjoins the margin only a confused and unnatural effect is obtained. The effect is very easily demonstrated by trial, and once it is known to exist the effect of the whole slide is spoilt. Similarly confused effects can be produced at the sides of the picture, and, as a matter of fact, this fault can often be found in commercial stereoscopic slides. If the combined picture seen in the stereoscope has not quite clearly defined margins, we may be quite certain that the trimming is at fault. In cases where very widely separated lenses were used a different kind of confusion often exists at the margins, but this is a separate matter altogether, and the effect can easily be distinguished. With normal separation of the lenses clearly cut margins should always be apparent, and the rule we have given in the *ALMANAC* affords the surest means of securing them.

#### Cheap Illustration.

A competition for the best photograph of portraits and other subjects is announced by the "Girl's Own Paper." Prizes amounting in all to twenty-seven guineas will be awarded, and in the case of a reproduction of a photograph to which no prize is awarded, it is stated that "remuneration in the ordinary course" will be sent. It would be desirable to have this phrase replaced by a more definite statement. The above wording and the announcement that no limit is set to the number of photographs that may be sent in by one competitor suggests that the "Girl's Own Paper" is seeking cheap illustrative matter for its pages and for those of the other publications of its proprietary, The Religious Tract Society. In fact, we read the positive condition that any photograph shall be reproduced, if so desired, in any publication issued by this religious body. The Religious Tract Society would certainly do well to make it clear that its competition is not of the "something for nothing" class by which other publishers have reaped a rich harvest from unsuspecting amateurs.

#### THE ADVANTAGES AND DISADVANTAGES OF TIME DEVELOPMENT.

NOTHING so damages the prospects and discounts the real merits of any new method or process as indiscreet and unjustified claims on its behalf. At the present moment there seems some danger of this happening with regard to time, or tank, development. The ordinary, matter-of-fact worker, having given unquestioning credence to extravagant statements as to the universal capabilities of this method of development, when he finds by bitter experience that these are not borne out in practice is inclined to regard the whole system as a delusion and a snare. It may not, therefore, be out of place or untimely to consider, without favour or prejudice, just what time development will do; and, on the other hand, what it will not and cannot do.

For a series of practically uniform exposures, such as a

number of snapshots taken successively under identical conditions, there is a distinct advantage in time development. The negatives or films will be clearer and free from fog than if exposed to the ruby light. There is a saving of time and trouble, the whole operation is more easily and automatically performed. The result, too, will be thoroughly satisfactory from a technical point of view, providing the exposures have been correct. An inexperienced amateur is more likely to secure negatives of even density and good printing quality by this method than by any which bring his own fallible judgment into play. To judge by the large number of tanks and developing machines now sold, the amateur has been perfectly aware of this fact, and is turning it to account.

If, however, the worker is tempted to adopt the time system under all circumstances, without allowance for varying factors or exceptional conditions, a disilluminated speedily takes place. The too common statement of its advocates that it will give the best possible result in all exposures, whether insufficient or excessive, and in all manner of subjects, cannot be substantiated, and is against the accumulated testimony of experience.

Most of us have learned to acknowledge the accuracy and the uniformly successful results which characterize the Watkins factorial system of development. There is a prevalent impression that this method and that of time development are, if not actually identical, at all events so much alike as not to be distinguished, and that they are founded on equally sound premises. This is not the case, as a little reflection will show. The factorial system makes allowance for differences of exposure, the negatives being developed for different times, as indicated by the time of appearance. The timing method makes no such allowance, but treats all exposures as alike. The two systems cannot be compared.

It is argued by the advocates of time development that the best possible result is obtained with under-exposed negatives, since over-developing and hardness are avoided and that nothing is lost, inasmuch as no means at present known will bring out the detail which is absent. The latter statement is certainly true; but can we ever be sure with the timing system, that the maximum of sharp detail has been brought out? This seems very unlikely if the plate is only developed for the time of a correctly exposed negative, considering the much greater slowness with which development proceeds in under-exposure. Then, again, an insufficiently developed under-exposed negative loses density in the fixing bath to a great extent than the normal, and this loss is greatest in the parts we most wish to preserve—the shadow details. Intensification of such an unduly thin negative will not supply the detail that has been deliberately thrown away. Then, as regards over-exposure, we are told that the time system will give practically the same result as the factorial recommended by Mr. Watkins, of increasing the time to about half as long again as that indicated by the time of appearance, and afterwards reducing with cyanide and hypo. This is not the case. Even supposing that the length of development by the first method was equivalent to that suggested by Mr. Watkins—and that no means follows—the omission of reduction will make a very great difference, since Farmer's reducer increases contrast, by attacking the shadows and half-tones to a greater extent than the lights. In other words, the time system flattens an over-exposed negative, while the factorial method improves vigour and contrast and tends to preserve truth of gradation.

It has been stated that by exposing several plates to a standard subject, giving each a correct and ide

ure, and developing these for slightly different times, I be easy, after fixing, to decide what is the correct of development for a properly exposed plate at a temperature. This is, of course, true. But the rates of time development go on to make the curious indication that correct exposure is absolutely essential, that information derived from incorrectly exposed is sure to be misleading. Precisely so! But does is undermine the whole argument that all exposures, t or incorrect, may safely be developed for an al time? If an incorrectly exposed plate is no t to the time of development of a correctly exposed t must follow that a correctly exposed plate is an y bad guide to the time required for developing an et exposure.

uncertainty does not end there. Even when we are n of the constant composition of the developer and of tant temperature, neither of which are so easy of ment as might be thought, we are assured by the manufacturers that the time of development will in different batches of the same plates, and also ing to their age and conditions of storing. Fac- development automatically allows for all these differ- time development does not. An advocate of the

latter system makes the significant admission that although a perfectly printable series of negatives can be secured by the uniform development of varying exposures, it does not follow that they will all be suitable for the same printing process. They will, however, undoubtedly suit some printing process. The professional worker, at any rate, will much prefer to see what he is getting, and to print his negatives, as far as possible, according to his preconceived intentions.

It follows, from what has been said, that for a series of uniform exposures, correctly timed by meter, on the same batch of plates, time development, if not the ideal system, is at any rate labour saving and perfectly satisfactory. For all kinds of work done in quantities with practically identical exposures, for various scientific and experimental purposes, or for the manipulation of panchromatic plates, it is strongly to be recommended. But for dealing with a mixture of subjects, problematic exposures, those having marked contrasts of light and shade, or, in fact, the generality of professional purposes, portraiture, architectural work, press photography, etc., the time system of development can only lead to disappointment and inconvenience. Still more must this be said of pictorial work, where truth of tone and gradation are valued.

## CANADA AS A FIELD FOR PHOTOGRAPHERS.

### II.

#### British Columbia.

sh Columbia marks the western limit of Canada. It is tainous country of great extent, with many fertile which are very favourable for all agricultural pursuits, owing being perhaps the most interesting at present. e mineral wealth of the country that has attracted the attention, gold, silver, lead, iron, and coal being found ned in large quantities. At the coast the climate is d moist. Nearly every variety of climate can be found province, excepting, of course, that of a tropical or opical nature. There have been many labour troubles, present the influx of Japanese and Hindoos is causing rious concern, not only in the province, but in the Canada. Their presence makes it difficult for a white obtain employment in the callings which do not require n the fisheries, in the hotels and restaurants, the men have nearly all been driven out by this cheaper It is a country of wonderful resources—which are eveloped in spite of these difficulties. There are perhaps eople of United States origin than in any other province, ir business methods and requirements are more akin States than Eastern Canada. Vancouver, population and Victoria, the capital, 25,000, are the two largest

#### Canadian Railway Development.

ailways of Canada are a very important factor in its evelopment, and no account of the country, however n very well omit some mention of them. The Canadian Railway, or the "C.P.R.," as everyone in Canada calls nds from the Atlantic to the Pacific, and with its ranches makes a system of over 9,000 miles, the greatest under one management in the world. It is the one atinental road at present, but there are under con- two other systems—the National Trans-Continental and the Canadian Northern, the former being built Government and to be operated by the Grand Trunk Railway, which is closely identified with the present stem of the Grand Trunk. The latter has already in

operation many links of its proposed line across the continent. All of these railways are extending their branches into new territory. There are two Government-owned railways—the Intercolonial, running from Halifax to Montreal, owned and operated by the Dominion Government, and a short railway into the Cobalt mining region, owned and operated by the Government of the province of Ontario.

#### Photographers' Opportunities.

In all these western provinces there are, and will be, openings for photographers. Success will come to the man who grasps the conditions and understands the requirements of the people. The average grade of work—at least along the main line of the C.P.R.—is high; as good, if not better, than the average work in Toronto and Montreal. The plates, paper, mounts, are almost exclusively of Canadian (Eastern), or United States manufacture, the prevailing styles, if such a term can be applied to photographic work, are wholly American, and a man starting business without a knowledge of these special conditions would be seriously handicapped. It would be almost essential for a man intending to start business in any part of Canada to obtain a position in an established "gallery," as the photographic studios are called, learn the conditions, and at the same time be on the look-out for a desirable location by getting in touch with the travellers (travelling salesmen) of the stock houses, as the dealers in photographic materials are termed.

This advice will also apply to apparatus. A man can decide better when he is on the ground what lenses and cameras he will need than he can in anticipation, and when he is not wholly familiar with the conditions. Some of the equipment can be purchased for less money in Canada than it would cost to import from Britain, though most of the lenses used in Canada come from there. Good lenses can be purchased in England for considerably less, and are comparatively easily carried.

#### Qualifications for Berths in Canada.

There are openings for portrait operators, printers, and commercial photographers in Canada, but the men must know

their business, but not too well. Good men will have very little difficulty in getting placed. The general experience of Canadian photographers with British help has not been at all satisfactory, mainly because the greater number have been incompetent. They do not try to learn the methods of their employer because "that is not the way they did it in England," and when given a free hand in printing and toning often turn out a batch of prints that are not fit to go out. As one photographer said to the writer, a certain batch referred to "looked as if an amateur had been trying his hand at it."

Most photographers in Canada, however long they have been at the business, are always ready to learn of and adopt a better way of doing the work, but the new hand should become proficient in his employer's methods, and then, if he knows he can improve on it, he will surely be given a chance to demonstrate the fact.

Perhaps the typical Canadian photographer in business is too cock-sure, but if his new helper from over the sea is inclined that way he had better dissemble until he has "made good." The man who pays has perhaps some justification in wanting things done in the way he believes the best way. In regard to wages, in Central and Eastern Canada a printer will get from \$9.00 (36s.) to \$15.00 (60s.) per week. A man who can operate, retouch, print, and finish if occasion requires it, is paid from \$12.00 (48s.) to \$18.00 (72s.) per week; some high-class portrait operators get from \$15.00 (60s.) to \$25.00 (\$25).

#### Kinds of Work—and Prices.

In the better class of portrait work collodion paper with a "carbon" finish (Aristo-platino) is almost wholly used. It is toned with gold and platinum. However, the use of some superior grades of gaslight paper is increasing. Cheap work and commercial work is largely finished in a gelatine printing-out paper, though gaslight paper is often employed. The highest quality work, however, is printed in black or sepia platinum. Carbon is rarely used.

Prices for finished portraits vary very greatly. In Ontario small sizes, less than c.d.v., will go as low as 50c. (2s.) per dozen, in the low-priced galleries, while sizes around the quarter-plate run from 75c. (3s.) up to \$2.50 (10s.), while cabinets range from \$1.00 (4s.) up to \$12.00 (48s.) per dozen, \$4.00, \$5.00, and \$6.00 (16s., 20s., and 24s.), however, being considered a good price for fairly good work, \$7.50 up to \$12.00 (30s. to 48s.) being obtained only by a few of the higher-class photographers who have made a reputation among the more fashionable element. For large work it is difficult to give a scale of prices.

In Manitoba and the West, the prices for average work are nearly double what they are in Ontario, while wages are only about 25 per cent. higher. The sparser population and greater cost of material will perhaps not give the photographer a greater profit.

#### Living and Clothing.

In regard to the cost of living in Canada, rents in cities are high in good localities, both for the student residence. In the smaller towns the rents are quite reasonable. Food costs about the same in Ontario as in England; perhaps less. Clothing, nearly twice as much. The higher wages in the West represents pretty accurately an increased cost of living. It is perhaps desirable for any coming to Canada with the intention of settling in the West to bring a good supply of clothing. In the case of men it is not much danger of being out of style for some time, but this cannot be said for women's clothing. The average Canadian dresses well—better than the same class in England. A woman might soon find what she considered attractive in England become very ordinary or peculiar when contrasted with the clothing of her new acquaintances.

Almost anything can be got in Canada in the way of clothing with very little trouble; the advantage one would have in getting here, of knowing what is suitable and what is fashionable, will more than offset the increased cost.

In regard to taking up land, and growing grain, cattle, or fruit farming, men from the older provinces, from Britain or other parts of Europe, have been successful, although without experience, or at least with very little getting to the Western country. This can be done again by those of considerable adaptability, with determination and hard work. Some capital is essential. The free land is becoming more inaccessible, railways and land companies having obtained great areas. They are selling these at reasonable rates. Full information about land, and the facilities, can be obtained from the offices of the Canadian Government or the Canadian Pacific Railway in London.

The marvellous resources of the country are being vigorously developed, but though substantial progress has been made, it can still be said that this has really only begun. The financial stringency of last year checked it very slightly; the prosperity of the country is real and sound, perhaps more so now than before tight money induced greater caution and care. The outlook for the future is full of the greatest promise.

Those in older Canada are continually hearing of immigrants who have become prosperous in the West. These good news are taking increasing thousands there every year. It certainly seems the land for young men. Britons have made their mark in the world over; they are doing so in Canada, and why not in its land of promise, the North-West?

There does exist in Canada a certain amount of prejudice against British immigrants, particularly Englishmen, due to so many incompetent people sent out by the charitable (?) organisations. This will have to be rectified by those who come out. The man or woman who is not afraid to work, and forgets for a little while how everything is in England, will be cordially welcomed, and will find as warm hearts and kindly faces in his new country as any place in the world.

DAVID J. HOWE

#### CONVENTION LYRICS, No. 4.

The old monks of Villiers-la-Ville,  
Of all life's good things had their fill;  
They relished good jokes,  
And good wine, and good smokes,  
And *peut-être* are enjoying them still.

P.S.—(To the Editor).

"Re last week's B.J."—To a certain extent,  
Your charming young lady is wrong;  
G H E N T, Sir, should be pronounced *Ghent*,  
It's G A N D that's called *Gong*.

BOLT COURT LECTURES.—A course of four lecture-demonstrations on "The Chemistry and Physics of Colloids, their Relation to Graphic and Photo-mechanical Processes," will be given at the School of Photo-engraving, Bolt Court, on Thursday evening 7.30 p.m., from June 4 to 25, 1908, inclusive, by S. E. SHEPHERD, D.Sc. (Lond.), F.C.S. Admission is free to students of the School, to others the fee for the course is 2s. The syllabus is:—"General and Characteristics of Colloids," "Reversible and Irreversible Colloids," "Preparation and Analysis," "Jellification and Coagulation," "Methods of Investigation," "Ultramicroscopy," "Dyeing and its Relation to Colloidal Phenomena," "Absorption of Inks, Dyes, and Pigments," "Absorption and Solid Solution."

## THE WATKINS METHOD OF CORRECTION FOR TEMPERATURE IN TIME DEVELOPMENT.

development—as distinguished from factorial development—has been much talked about of late. As our readers know, it is only understood to be development for a fixed time, which is based on preliminary trials for a given plate, a given developer and given temperature. Change one of these three, and the time of development must be changed. “Factorial development,” on the other hand—i.e., the method of calculating the total time of development from the time required for the first appearance of the image, for one, two, or all three of these items being changed without affecting the practice of the method. Mr. Watkins, it is well known, has hitherto given his adherence chiefly to the “factorial” method, but he has now devised a commercial system by which it is said the “time” method becomes easier in practice than the factorial method—as easy, in fact, as timing an exposure by the stop meter. The system is the result of Mr. Watkins’s recent experiments in testing the rapidity of development of commercial plates. Its practice involves the use of—

the Watkins ready-made one-solution developer.  
the Watkins list of commercial plates classified with regard to time of development.

latter, as we mentioned last week, divides plates into seven classes according to their speed of development in the Watkins system. Thus two of the factors necessary to a system of development—time—plate and developer—are accounted for. The third factor, temperature, and this Mr. Watkins provides for by affixing to the list of developer a simple calculating scale, by which the time of development for any reasonable temperature can be found. The result should be to give universality to a method which is now based on the basis of quite special data. In other words, one of the Watkins developer and calculates—or, rather, has calculated—one—the time for which a plate of any make should be developed at any workable temperature to give a negative of a degree of contrast. Our supply of developer reaches us from the Watkins Meter Company just in time for us to give this introduction of the new introduction. As we point out in another article, we are not wedded to time development as a method. It is undoubtedly its advantages—for the less practised worker partly—and it equally has its limitations. These latter are, certainly, to a great extent, removed by Mr. Watkins’s new system.

Following are the complete instructions issued by the Watkins Co. for the use of their new developer, and the practice of the new system:—

Development needed in development can be exercised almost entirely by development, a short time tending to softness or least contrast while a longer time tends to vigour or greater contrast—in other words, hardness. If the developer is kept uniform (as it is in this system) the only influences which cause alterations in the right time to give a given amount of contrast, are plate and temperature.

### Plate.

Plates require five times the development of others to attain the same contrast in the negative, and these variations are indicated approximately in the speed card. In the present state of plate development, the development speed of a plate (a quality quite distinct from exposure speed) is apt to vary considerably with different plates; and the time indicated by the speed list must only be taken as a first trial, to be altered if found advisable. Plates are also liable to “go off” with keeping, and this change may result in a longer time. Some plates have not a coating capable of giving a full amount of contrast; and increased time of development will not in such a case increase contrast beyond a certain point. In the V.S. class are most liable to this peculiarity, which for the work may possibly be a convenience, not a defect.

### Temperature.

Up to now, most instructions have shirked this matter by giving the simple advice to “always develop at 65 deg.” With the Watkins system, a simple thermo indicator is provided on the bottle,

which shows the time variation for all temperatures; and development may be at the natural temperature of the dark room. This is based on Mr. Fergusson’s temperature formula. Development at 45 deg. is about three times as long as 75 deg.

It will be seen that the extreme variations for both plate and temperature combined can amount to as much as fifteen times, and this applies equally to stand or film development; and the want of some systematic method, as here given, is plain.

### Apparatus Required.

Developing and fixing dishes. An ounce measure (2 oz. for quarter-plate use, or 4 oz. for half-plate use). A dram measure (2 dram for quarter-plate use, or 4 dram for half-plate use). A thermometer—the common house or garden type—to hang in dark room is sufficient; but if buying one, get one capable of dipping in liquid. A cover (cardboard will do) for developing dish. A light in room capable of turning up and down. A Watkins dark room clock is not a necessity, but a great convenience, as its minute divisions are six times the size of those on all other dials of the same diameter. The dark room light is not necessary with a little practice at having appliances ready to hand to handle in the dark. A jug or bottle of water to be kept in the dark room beforehand, and not drawn from a tap of different temperature.

### Instructions.

First, agitate the bottle (so as to mix its flocculent deposit), by turning upside-down three times—this is better than violent shaking. For every ounce of developer wanted, measure one dram in the small measure; pour this into the larger measure, and fill up with water to the ounces required. Thus, for quarter-plate, take 1½ drams, and fill up to 1½ ounces with water; for half-plate, take 3 drams, and fill up to 3 ounces. The diluted developer will be clear in about a minute. Dilute only just before use; do not make up a diluted stock. Turn down light, put plate in dish, pour on the developer (tilt the dish), cover the dish, and turn up light; note the time, or start the clock at once.

Look out the development speed of the plate on the speed card, for the first trial development. The following is the time for 60 deg.:  
V.Q., 2½ min. Q., 3 min. M.Q., 4 min. M., 5½ min.  
M.S., 7 min. S., 9 min. V.S., 11½ min.

But the time for the present temperature is probably different. Take hold of the movable paper ring on the bottle (the thermo-indicator) with the finger and thumb on the discs, and revolve until the pointer 60 indicates the time suggested in the above table. Note the actual temperature of the room, and against that temperature on the scale the minutes to develop are indicated.

Example:—Q. plate; pointer to 3 minutes; temperature 54 deg.; result is 3½ minutes.

Develop for the indicated time, and if after fixing and printing, the print has insufficient contrast, take in future a longer time (say 3½) as the “60 time” for that plate. If the print has too much contrast, take a shorter time for the “60 deg. time” in future. Another method is to develop in any accustomed way, by inspection for the first trial, noting the time occupied, also the temperature. Set this temperature against the time on the thermo-indicator, and then note, for future use, the 60 deg. time against the pointer. After the first trial the pointer can always be set to the “60 deg. time,” found right; and any time, for any temperature, can be read off; as temperature will change from time to time. Take care to wipe the mouth of the bottle after pouring, as a drip of developer will destroy the calculating label and band.

### Variation for Printing Process.

If a negative has a contrast suited for P.O.P., a slightly longer time—say three of the temperature two-degree divisions on the scale—will be right for carbon printing. A shorter time than for P.O.P. will be best for enlarging, or gas-light printing—say three of the two-degree divisions on the temperature scale.

### Variation for Subject.

This is seldom needed, as a right standard time gives the amount of contrast seen by the eye, whether there is a large contrast in the

tones of the subject—as in a street scene—or a small contrast—as in a distant landscape. But if it is especially desired to subdue the contrasts seen in the subject, give a shorter time than the standard. If, on the other hand, it is desired to emphasise the contrasts as seen, give a longer time than the standard. Stereoscopic negatives should receive only  $\frac{2}{3}$  time; sky negatives about half-time; copying black and white,  $1\frac{1}{2}$  times.

#### Use of Bromide.

There is no bromide in the developer, and it should not be added except for known over-exposure, or to keep back fog, if the plate (or dark-room light) tends to it. Fortunately, the addition of bromide does not alter the time required for a given contrast. It practically lowers the speed of the plate, and holds back (for a time) the lowest tones and fog. The amount required depends upon the amount of fog or over-exposure to be counteracted, and varies, from 1.5 grain (2 minims 10 per cent. sol.) to the ounce, to 2 grains (20 minims 10 per cent. sol.) to the ounce. To make the "10 per cent. solution," dissolve 1 ounce potassium bromide in water and make up to 9 oz. 1 dram. Every 10 minims (or drops) of this equals 1 grain.

#### Factorial Development.

The developer is perfectly suited for this method, its factor being 15. It must be clearly understood that the thermo method and the factorial method are distinct ways of timing development. When timing by factor, neither the thermo scale nor the speed card classification is used. To develop by factor use a dark-room light. Pour on the developer, noting the time by watch or clock, and commencing to count seconds. Carefully watch the plate, and note the first trace of an image in the high-lights. This number of seconds is the "time of appearance," and fifteen times this is the total time of development, from the commencement. If the seconds appearance is divided by four, the result is the minutes to develop. For full details of the method consult the Watkins Manual. If bromide is added, the factor is less than 15. The factorial method may be used to ascertain the development time for the first trial of a plate, afterwards using the thermo scale for allowing for variations caused by temperature. When this is done, the temperature of the first trial must be noted and set against the time of development (if found correct) on the thermo scale, which is then at its correct setting for future use with the plate. If a note has to be made of this setting, note the time opposite the pointer 60.

#### Stand or Tank Development.

The thermo method is admirable for any of the numerous tanks and development machines now sold, whether for film or plate, and

the development speed on speed card can be used. Develop at natural temperature of the room (notwithstanding tank maker's instructions to the contrary), as the thermo scale will make allowance. Provide beforehand a large jug of water to attain temperature of the room. The quantity of developer required is large, it must be used diluted. This increases time, and the dilution is a little more than the dilution. The most convenient dilution is four times, and this multiplies the calculated time by  $4\frac{1}{2}$ . How many ounces the tank requires up to its filling mark; run out one dram of concentrated developer for every four ounces required. Pour this into the tank, and fill up with the water to the mark. Calculate the development on the scale, and give  $4\frac{1}{2}$  times this.

Example:—Kodak film S., is 9 minutes at 60 deg. But the temperature is 72 deg., and the time for standard dilution is 6 min.  $4\frac{1}{2}$  times this is 27 minutes, which is the time to develop for the standard dilution. In all tank development it is most important either the developer is moved over the surface of the plates two or three times during development, or that the plates are moved in the developer; otherwise development is uneven. Construction of the tank decides this. Either lift plates or flip out of developer and replace them at once, or turn the whole upside-down several times.

#### Fixing.

Dissolve 4 ounces of hypo in 20 ounces (a pint) of warm water. Soak the negative in this, in a dish, for twice as long as any appearance remains in the plate. Wash in running water for an hour and dry.

#### Development Papers and Autochrome Plates.

For these a little potassium bromide (say 5 minims of the 10 per cent. solution to the ounce of complete developer) should be used. It is considered best to use the developer double strength for gelatin papers—that is, 2 drams to the ounce.

With any developer the time should be varied for temperature. The Watkins developer is perfectly efficient for the first development, adding  $\frac{1}{2}$  grain bromide to the ounce, and gives the power of allowance for temperature. The 60 deg. time is 7 minutes. Lumière's formula or (practically the same) any amidol developer should be used for the second development; not a developer containing alkali in it. Plates should not be handled, but left in dish processes, and for each intermediate washing. If frilling the edge the next plate with solid paraffin wax melted in a tin dish, a spirit lamp, and standing  $\frac{1}{4}$  in. deep. When a Bee meter or Autochrome dial is used, we do not think there is any need of varying time to suit varying exposure.

## THE COLOUR-FILTER AND THE "ISOCROMATIC" PLATE IN ASTRONOMICAL PHOTOGRAPHY.

### II.

In a paper by Dr. Schlesinger in the "Astrophysical Journal" of 1904 (20, 123) dealing with photographic star-images for parallax determination, an illustration is shown of a loose cluster taken with the 40-in. telescope, on an isochromatic plate, *without* the interposition of a colour-screen. In this plate the enlargement is so slight—1.7 times—that the quality of the images cannot be shown. Besides, such an enlargement is in no wise comparable with that required in lunar or planetary work. A number of illustrations are therefore given (Figs. 4 and 5) of series of exposures made at the 40-in. telescope upon the same star, both with and without a colour-filter. The exposure times are 30 sec., 1 min. 30 sec., 4 min. 30 sec., and 13 min. 30 sec., and the enlargement is rigorously exact on each to eight diameters. The statement by Schlesinger that "careful comparison of stellar plates, taken with the screen and without, shows that there is little to choose between them, either as regards the minuteness of the images or their sharpness," cannot therefore be accepted. It should be said, however, that his comparisons were on negatives made by Ritchey with a colour-filter which transmitted a considerable amount of blue light, extending almost to  $\lambda 4500$ ; also, his statement applies particularly to faint stars, which in reality do present but little difference unless they be much enlarged.

During the period covered by the past fourteen years the author has given considerable time to the special study of absorption for various conditions, and in 1903-4 devoted much labour to critical requirements necessary in filters for astronomical photography. Use was made of the 12-in. and 40-in. telescope about 500 lunar and stellar negatives were made at various times throughout that period. These negatives were made under all possible (logical) variations of the colour-filter, both "liquid" and "solid," and of mean transmission of from  $\lambda 4200$  through many stars to  $\lambda 5500$ . Some of these filters also absorbed the red end of the spectrum. This large number of negatives contained some excellent choice images which were selected and the filters located in a laboratory notebook. Deductions from these results showed that with a range of 100 tenth-meters within the limits of  $\lambda 4700$  there was no certain improvement discernible on the delineation of detail when the exposures were at the minimum allowable normal development, although, as has been stated, *theoretically* they should increase in value as the filter approaches isochromatism.

Fig. 6 shows the transmission spectra of several of the filters used at this observatory, while Fig. 7 shows the diffraction

the images obtained with practically similar exposures by use of filters  $\lambda 4600$  and  $\lambda 4900$  respectively. Between these two there is noticeable a gradual increase in quality value of the images as they approach nearer to monochromatic conditions. The image in most general use here possesses a mean absorption of  $\lambda 4900$ . The justly famed lunar negative made by Ritchey the densest

filter used by him transmitted blue light as short as  $\lambda 4500$ , the seeing was so good, and the exposures were so successfully made, that, from the comparatively small number made, he was enabled to select several that show a delicacy of detail which, though inferior to visual observations, has given them the premier place in photographic lunar delineation. Had the exposure been made it would have been at the expense of definition—the sum-

Fig. 5.

the effect of the action of the blue light and the atmospheric seeing. In a recent paper by Professor Lowell<sup>6</sup> there has been advanced the terms a "new means of sharpening celestial photographic images," and the paper is illustrated by diagrams, to show the effect of colour-sensitive plates, and of the Lowell objective respectively. The title is misleading, however, because fallacious, being based upon a misconception of the theory.

<sup>6</sup> "B.J." 1907, p. 977.

Briefly expressed, the "device" consists in sensitising an isochromatic plate for the red, and making use of a colour-filter with an absorption at  $\lambda 5000$  (made by the writer). His first illustration shown represents the colour curve of the Lowell 24-in. objective, but the curve shown by Lowell differs considerably from curves supplied me for the construction of his colour-filters, and differs

Fig. 6.

Spectral transmission of various colour-filters.

also from that published by Slipher in the "Astrophysical Journal."<sup>7</sup> This lack of accordance is shown in the illustration (Fig. 8), where it will be seen that there is an ordinate difference of from 5 to  $7\frac{1}{2}$  units at the Fraunhofer C and B lines. A close search fails to find anything published regarding a redetermination of the curve later than that already published by Slipher.

The second illustration is entitled "curves of sensitiveness of photographic plates" (Fig. 9a), but as such they are unfortunately quite wrong.

Fig. 7.

Difference in quality of star images with colour-filters absorbing at  $\lambda 4,600$  and  $\lambda 4,900$  respectively.

Taking that one plotted as the "Cramer instantaneous isochromatic" and comparing it with the actual sensitiveness curve plotted from careful measurements as shown by the dotted line (Fig. 9b), the result serves well to show the futility of plotting densities from visual estimates.

The two Lowell curves shown extending into the red beyond B,

<sup>7</sup> 20/9/1904.

are marked respectively "Seed 23 bathed with pinacyanol and pinaverdol," and "Seed 23 bathed with pinacyanol and pinachrome." The context of the paper informs us that a trial of these two plates thus treated resulted in failure, the cause for which it is suggested may lie in the developer used. Inability in the present writer to follow the reasoning which prompts this suggestion, leads, however,

Fig. 8.

to discarding the attempt, when it is obvious that the failure follows inevitably from the slowness of the plate and the "flatness" of its sensitiveness curve between  $\lambda 5000$  and  $\lambda 6800$ . As failures, however, the value of their inclusion is doubtful, while as representing relative sensitiveness they are deficient. The "blue-sensi-

(Ordinate values were not indicated.)

tiveness" of a plate divided by the "yellow (or red) sensitiveness" is the method adopted by all photographic workers for expressing the chromatic value; and following this, measurement of these curves gives a value of about 1.2 or 1.3, while in reality the true value lies in the neighbourhood of 11.0 or 12.0.

In all probability a part of the difference is due to the fact that the Lowell curves are estimated from prismatic spectra—a most unre-

liable source, because the apparent sensitiveness is shifted toward red end by an amount dependent upon the refractive index number of prisms used. Every investigator in photography knows that the maximum sensitiveness lies at  $\lambda 4100$ , not at  $\lambda 4600$ , and in fast isochromatic plates of high quality the value of the yellow-green sensitiveness is far below that of the blue-sensitiveness, not in excess, as shown in the Lowell curves. What we are immediately concerned with, however, is the relative sensitiveness of isochromatic plate after bathing.

If it were possible to sensitise an isochromatic plate for the red and retain the relatively high maximum of sensitiveness in yellow-green at  $\lambda 5600$ , then, in reality, we should still occupy same position in regard to celestial photography as before; but although it would be possible to gain greater speed it would be at the expense of definition; for it stands without possible argument, and, as has been shown, that the greater the extent of object curve embraced, the less critically sharp the image; although

Fig. 9B.

consequent reduction in exposure time there would be less liable to unsharpness by waves of bad seeing. It is unfortunately, however, that it is impossible to retain the value of the original chromatic maximum.

Supplementary to a somewhat exhaustive investigation upon action of the isocyanin dyestuffs upon the photographic recently concluded by the author,<sup>8</sup> about a dozen isochromatic plates were bathed in a combined bath of pinacyanol and chrome, under different types of bath, which included water, dilute alcohol, plus ammonia, with subsequent washing in water, alcohol, dilute alcohol, and without washing. The strongest sensitising action with this plate was found to result from an ammoniacal bath followed by a slight water washing, and rapid drying. The plate was then developed in the constant temperature tank, fixed, dried, measured, and plotted. This is the curve shown by the continuous line in Fig. 9b.

ROBERT JAMES WALLACE

(To be continued.)

<sup>8</sup> "Astrophysical Journal," 26, 299, 1907 ("B.J.," January 31, p. 83, February 10, p. 101, and February 14, p. 119, 1908).

THE HOLIDAY "WHITAKER," which differs from most guide books in having both a summer and winter edition, certainly appears to justify its claim to be an illustrated guide to the health and pleasure resorts in the United Kingdom. The summer edition, just to hand, gives, for the small sum of 1s., much useful and instructive information respecting the various towns, villages, etc., both inland and on the coast, which offer special attractions, either in the way of health or pleasure to holiday makers and tourists, the alphabetical arrangement of names reducing the work of reference to a minimum. The visitor from the country to London also is not forgotten, one section of the book being devoted to "The London of 1908." The sections devoted to sports and recreations of various kinds are too numerous for us to mention here, but intending holiday makers will, we think, do well to obtain a copy of the book from the

publishers, Messrs. J. Whitaker and Sons, Ltd., 12, Warwick Lane, London, E.C.

THE HALL-EDWARDS FUND.—The Imperial Yeomanry School Committee have forwarded to Mr. Oliver Williams, secretary to the treasurer of the Imperial Yeomanry Hospitals, a cheque for towards the fund which is being raised for Mr. Hall-Edwards X-rays victim. This brings the total of the fund up to £1,956.

INFORMATION FOR HOLIDAY MAKERS.—The latest additions to series of booklets which the Health Resorts Development Association of 29, John Street, W.C., publish for the various Town Councils, with the districts of Malvern, Leamington, Weymouth, and Wood Spa, and copies may be obtained, post free, by applying to the respective Town Clerks.

# AMMONIUM THIOSULPHATE AS A FIXING-BATH.

Ammonium thiosulphate, the use of which was first advocated as a fixing agent in 1868 by John Spiller, has been recommended by writers since that date as a substitute for the common hypo solution of sodium thiosulphate, on account of the advantages which the ammonium salt possesses over the sodium compound. According to authorities the most important advantage consists in the greater rapidity of action. The greater solubility of the ammonium compound has been claimed also as advantageous in respect of removal of fixer by washing; spots or streaks on the films of plates after having also, it is claimed, no tendency to appear when ammonium salt is used.

For a long time this fixing agent was not used on account of the desiccating character of the crystallised salt, and attention was thus directed towards efforts to use the ammonium thiosulphate in admixture with other compounds, such as ammonium sulphate or ammonium chloride. Different mixtures have been recommended, but hitherto no one does not appear to have gained favour in comparison with plain hypo. The following experiments have, therefore, been made in order to ascertain the facts as to the action of a mixture of hypo and ammonium chloride, and to ascertain also whether this mixture can or cannot be used with advantage as a substitute for plain hypo.

The questions which we had in view when making our experiments were as follows:—

1. The proportion of hypo and ammonium chloride to secure most solution of silver bromide.

2. The solubility of silver bromide in this bath at different degrees of concentration in comparison with the plain hypo bath.

3. The stability of the double salts formed in the fixing bath in comparison with that of the double salts of silver with sodium thiosulphate.

4. The extent to which the bath can be used in comparison with plain hypo solution.

5. The removal of the excess of fixer by washing or other more convenient means.

6. The effect of increasing proportions (2 to 20 per cent.) of ammonium chloride added to a 15 per cent. solution of sodium thiosulphate, and the effect of fixation noticed in each case. It was found that fixation was most rapid when the ammonium chloride was present in the proportion of one-quarter the hypo—i.e., 3½ per cent. With this proportion of ammonium chloride took place in one-third the time required for plain hypo. The time necessary for fixation increases with the proportion of ammonium chloride, and when this latter reaches 8 to 10 per cent. the favourable action as regards reducing the time of fixing can be considered.\*

7. The effect of increasing the concentration of the hypo solution is raised from 15 to 40 per cent. the difference between the time of fixing with ammonium chloride and that without, rapidly disappears as a stronger solution of hypo is added. With a solution of 40 per cent. the time of fixing with and without ammonium chloride is the same.

8. A question may be asked whether the speed of fixing is due to the greater solubility of the silver bromide, or whether it is a simple case of rapid diffusion, or, again, whether it is the result of the solution penetrating more rapidly into the gelatine film. To these matters the solubility of the silver bromide in different solutions under examination was ascertained, and the following results were obtained:—

Strength of hypo solution,	Silver bromide dissolved in 100 ccs. hypo solution, gms.	Silver bromide dissolved in 100 ccs. hypo solution, containing also ammonium chloride to the extent of 1/3rd the weight of the hypo, gms.
10	3.64	4.91
15	4.37	6.04
25	8.11	9.34
40	11.30	10.90

These results confirm those which we have already given in

the most advantageous proportion of ammonium chloride is distinctly less than that corresponding to the formation of ammonium thiosulphate according to the reaction  $\text{Na}_2\text{S}_2\text{O}_3 + 2\text{NH}_4\text{Cl} = (\text{NH}_4)_2\text{S}_2\text{O}_3 + 2\text{NaCl}$ . This mixture will correspond to a solution of ammonium chloride to 2,000 ccs. of 15 per cent. hypo solution, but the time of fixing is the same with 13 grams as with 7 to 8 grams of ammonium chloride. It is probable that a mixture of ammonium thiosulphate and sodium thiosulphate in suitable proportions would fix silver bromide just as quickly as ammonium thiosulphate alone.

reference to the quickness of fixing in hypo solutions of various strengths containing ammonium chloride.

In order to study the permanency of the salts which are formed on treatment with a mixture of hypo and ammonium chloride we prepared these compounds by forming a saturated solution of silver bromide in a solution which contained 250 gms. hypo and 110 gms. ammonium chloride per litre; in other words, the proportions required by theory to form ammonium thiosulphate. This saturated solution was filtered and allowed to stand, and deposited, after some time, transparent crystals insoluble in water, which contained sulphurous acid, silver, and ammonia. This is a double salt, doubtless the double salt of sodium and silver,  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , corresponding to that which is formed by the action of ordinary hypo on silver bromide. This double salt is unstable, blackening between 50 and 60 deg. C., and forming sulphide of silver. The clear liquor, on addition to half its volume of alcohol, throws down a white deposit of thin shining plates, resembling mother-of-pearl. These, on being dried, become dark on exposure to the air. The compound contains silver, ammonia, and sulphurous acid. A similar compound can be obtained when a saturated solution of silver bromide in ordinary hypo is precipitated with alcohol. We have shown that the double salt formed under these conditions corresponds to the formula  $2\text{Na}_2\text{S}_2\text{O}_3 + \text{Ag}_2\text{S}_2\text{O}_3 + \text{H}_2\text{O}$ , and that it is sufficiently permanent in damp air to give no darkening in contrast with the compound just described, as formed with a mixture of hypo and ammonium chloride. These results appear to show that bromide of silver gelatine plates or papers, which are fixed in a mixture of hypo and ammonium chloride, more easily undergo changes than if a plain hypo solution is used, unless the double salts formed in the fixing bath are completely removed by washing.

We have made experiments to find whether the degree of exhaustion to which the bath can be pushed varies with the composition of the baths in question. In all our experiments we have used the same volume of a fixing bath and have added to it constantly increasing quantities of silver bromide prepared in the dark and well washed. A drop of each solution was spread on a strip of filter paper and exposed for several days to the combined action of light and moist air. In every case the maximum weight of silver bromide was found which could be dissolved in a bath of thiosulphate without perceptible brownening, and the results of experiments made in this way are given in the following table:—

Fixing bath. In 100 ccs.		Maximum weight of silver bromide which can be dissolved in 100 ccs. of the fixing-bath without subsequent darkening taking place.
Hypo, 5 gms.	.....	1 to 1.25 gms.
" 5 "	+ Ammonium chloride, 2 gms. ...	25 gms.
" 15 "	.....	3.25 to 3.60 gms.
" 15 "	+ Ammonium chloride, 5.5 gms. ....	75 to 1.0 "
" 45 "	.....	5.0 to 5.25 "
" 45 "	+ Ammonium chloride, 19.5 gms. ....	3.3 to 3.25 "

If the pure sodium thiosulphate be used to a point beyond the limit of exhaustion there results a weak yellowish colour, which slowly increases as the silver bromide accumulates in the solution, whilst in the case of the mixture of thiosulphate and ammonium chloride a darkening of considerable intensity results, indicating a decided decomposition of the double salt. We have, lastly, decided the point as to whether the double salt of ammonia and silver can be more rapidly removed by washing in running water than can that formed by the double salt of silver and sodium. For this purpose a dozen sheets of bromide paper, 7 in. by 5 in. in size, were fixed in a 15 per cent. solution of plain hypo, whilst another dozen sheets of the same paper were fixed in a similar solution containing, however, also 6.5 solution of ammonium chloride. Each of these series of sheets was washed in running water, the conditions being kept absolutely the same. Every quarter of an hour a sheet was removed from each batch, and tested with a drop of silver nitrate solution which gave a spot of silver sulphide of greater or less intensity,

\* Lumière and Seyewetz, "Bull. Fr. Phot. Soc.," 1907. "B.J.," Feb. 22, 1907, p. 138; Aug. 16, 1907, p. 614.

according to the quantity of hypo contained in the paper. After several hours' washing no detectable difference could be found, on the test being made, between sheets of the two series.

The following are the conclusions from the foregoing experiments:

(1) Addition of ammonium chloride to hypo solution hastens the fixing of silver bromide plates and papers only when the proportion of the solution to thiosulphate is less than 40 per cent.

(2) The proportion of ammonium chloride which exerts the maximum of action as regards speed is distinctly less than the proportion theoretically necessary to form ammonium thiosulphate. If this theoretical proportion be exceeded the speed of fixing falls off.

(3) The solubility of the silver bromide in hypo is increased by addition of ammonium chloride if the strength of the thiosulphate is

under 40 per cent. On the other hand, it is reduced if this strength is reached or exceeded.

(4) The compounds of the silver salts which are formed in a bath of hypo and ammonium chloride are distinctly more unstable than those formed with pure hypo, and the degree to which they can be used is also distinctly less in the case of the compound salts.

(5) In spite of the advantages which a mixture of hypo and ammonium chloride possesses as a rapid fixing agent, it is to be feared that this method of fixing should be discarded, on account of the instability of the double salts, and the rapid changes which take place in the prints unless the washing is thorough.

A. AND L. LUMIERE.  
A. SEYEWETZ.

## ORTHOCHROMATIC COLLODION EMULSION.

Drs. E. STENGER and H. Heller report in the "Zeitschrift für Reproduktionstechnik" on their efforts to make a collodion emulsion which should equal the colour sensitiveness of the best commercial gelatine plates and not show minima of sensitiveness. The paper is very lengthy, but the following are the important points.

As the mother emulsion the authors chose von Hübl's ammoniacal chloro-bromide formula. Although this has been already given in our pages, we repeat the same in order that the information may be complete.

A. Colloidine .....	28 gms.
Alcohol .....	466 ccs.
Ether .....	234 ccs.

When dissolved add B:—

B. Silver nitrate (powder) .....	50 gms.
Liq. ammonia (sp. gr. .91) .....	50 ccs.
(This solution must be quite clear.)	
Alcohol (95 per cent.) .....	100 ccs.

When the solution has cooled down, if any crystals are formed add Distilled water .....

3-10 ccs.

In the dark-room now add C:—

C. Ammonium bromide .....	27 gms.
Warm distilled water .....	40 ccs.
Alcohol .....	100 ccs.
Lithium chloride (10 per cent. solution) .....	10 ccs.

The lithium chloride solution is made by dissolving 10 gms. anhydrous lithium chloride in 10 ccs. water and adding 90 ccs. alcohol.

C solution should be placed in hot water to prevent separation of the salts. It should be added in about fifteen portions to the silver collodion, within fifteen minutes, then shaken vigorously for three minutes and allowed to stand for two to four hours. It is then added to the emulsion slowly and in small quantities.

Distilled water .....

300 ccs.

Shake well, and pour the whole into about 3 litres of water, well stirring all the time.

The emulsion should be allowed to settle, the supernatant liquid poured off, and the precipitate washed five or six times by decantation. The shreds of emulsion should then be placed on a linen filter, drained, pressed free from water, and as much water as possible removed by repeated moistening with alcohol and pressing out.

The emulsion, which should now be a fine sandy powder, should be dissolved in

Alcohol .....	400 ccs.
Ether .....	475 ccs.

After standing a few days this emulsion works very clean, and has a far better gradation than a wet plate.

The emulsion should be shaken up with the required quantity of dye just before use, and the coated plate washed for three minutes in water, and immediately exposed. The developer recommended is:

Rodinal .....	10 ccs.
Water .....	186 ccs.
Potass. brom. (10 per cent. solution) .....	4 ccs.

To test the plates the authors used a spectrograph, with a Thorp diffraction replica. The light source was a Nernst lamp, and the slit width 0.4 mm., the exposures from 1-4 minutes.

The peculiar sensitiveness of this emulsion extended from  $\lambda$  460, with a maximum at about 340 to 440.

### The Fluorescine Derivatives.

The following table gives the most important results:—

Dye.	Sensitiveness Band with an Exposure of		Maximum Density.	Character of	
	1 min.	4 min.		Density.	
1. Tetrabromofluorescine .....	510-540	480-560	520-540	fairly good	
2. Diodifluorescine .....	520-565	500-575	535-565	strong	very
3. Dichlorofluorescine .....	520-560	515-565	530-560	weak	
4. Tetraiodochlorofluorescine ..	540-580	510-600	560-580	vigorous	very
5. Tetrabromdichlorofluorescine*	520-565	535-560	535-560	very weak	
6. Tetrabromfluorescine-ethylester	490-560	490-570	535-555	vigorous	very

\* With 15 min. exposure.

1. Known as Eosine A. The dye was recrystallised from a mixture of alcohol and water. The uncrystallised showed weaker action. 1 gm. was dissolved in 150 ccs. absolute alcohol, and 25 parts added to 1,000 parts of water.

2 and 3.—Same strength used.

4. Rose Bengal. Same strength as 1.

5. Phloxine extra. 1 gm. dissolved in 200 ccs. 75 per cent. alcohol. 33.3 to 1,000 emulsion.

6. Primrose. 1 gm. in 375 ccs. 80 per cent. alcohol. 62.5 to 1,000 emulsion.

Fluorescine or uranine A, tribrom-mononitro fluorescine, tetrabrom-dinitro fluorescine showed no sensitising action. Less than that given above gave less colour-sensitiveness, except rose bengal and phloxine: with these half the quantity gave as good sensitiveness. Increase of the dye reduced the actual sensitiveness of the plate through screening action. Arranged in order of sensitising powers the dyes are 2, 6, 4, 1, 3, and 5.

### The Cyanines and Isocyanines.

The results obtained with these dyes are tabulated below:

Dye.	Sensitiveness Band with an Exposure of		Maximum Density.	Character of	
	1 min.	4 min.		Density.	
1. Cyanine .....	530-635	510-655	550-630	strong	foggy and
2. Diethylcyanine .....	565-610	540-615	585-610	fairly strong	and
3. Diamethylcholinethylester (a - $\gamma$ ) ..	550-720	530-720	580-600	very strong	cl
4. Pinaverdol .....	495-610	480-630	490-550	strong	cl
5. Ethyl-red .....	500-615	485-630	500-600	strong	fairly
6. Pinachrome .....	510-650	510-660	540-570	strong	fairly
7. Isocol .....	510-665	500-685	560-595	fairly vigorous	fairly
8. Pinacyanol .....	520-700	500-710	570-680	strong	fairly

1. 1 gm. dye in 500 absolute alcohol. 20 to 1,000 parts of emulsion.
2. Same dye strength as 1. 2.5 to 1,000 parts of emulsion.
3. A new dye made by H. Auerbach in the photo-chemical laboratory of the Technische Hochschule, Charlottenburg. Used as No. 1.
4. 1 gm. in 1,000 ccs. absolute alcohol. 40 to 1,000 parts of emulsion.
5. As No. 1.
6. 1 gm. in 1,000 ccs. 70 per cent. alcohol. 40 to 1,000 of emulsion.

1 gm. in 2,000 absolute alcohol. 40 to 1,000 emulsion.  
1 gm. in 1,000 absolute alcohol. 80 to 1,000 of emulsion.  
Bathing the plate in a 1 : 3,000 solution of dimethylchinolin ethylate and subsequent washing for three minutes gave the same results of sensitiveness, but the density was much less.

### Some Azo Dyes.

Various dyes of this class were used alone or in combination with others. The results are given in the following table:—

Dye.	Sensitiveness Band with an Exposure of		Maximum Density.	Character of	
	1 min.	4 min.		Density.	Plate.
Longo red.....	—	520-580	—	very faint	fairly clean
Glycin corinth .....	—	400-600	—	very faint	clean
Glycin red.....	460-650	460-630	520-625	strong	clean
Thiazol yellow .....	460-575	460-600	450-560	strong	clean
Dimethylchinolinethylate + ethyl red	590-700	875-720*	820-545	very dense	clean
Glycin red + Thi-zol yellow	—	360-680	565-590*†	very dense	clean
Glycin red + Isocol .....	360-685	360-685	625-640 655-665	dense	fairly clean

\* Strongest minimum 460-590.

† Strongest maximum.

1. Benzidin-disazo-bi-1-naphthylamin-4-sulphonic acid. 1 gm. dye in 500 ccs. absolute alcohol. 40 to 1,000 emulsion.

2.  $\alpha$ -naphthylglycin-1-naphthylamin-4-sulphonic acid, recrystallised from 95 per cent. alcohol. 1 gm. in 500 ccs., 95 per cent. alcohol. 40 to 1,000 emulsion.

3. Benzidine-disazo- $\alpha$ -naphthylglycin-1-naphthylamin-4-sulphonic acid. This is only a good sensitiser in aqueous solution, but satisfactory results are obtained with 1 gm. of dye in 300 ccs. water and 300 ccs. absolute alcohol, of which 50 ccs. should be added to 1,000 ccs. of emulsion.

4. This dye was thiazol yellow G (Bayer), a diazo-amido compound of dehydro-toluidine-sulphonic acid. 1 gm. in 600 ccs. 80 per cent. alcohol. 80 to 1,000 emulsion.

The idea in using combinations of the dyes was to fill up the familiar gap in the blue-green. This was done in the case of 6 and 7. The addition of fluoresceine or thiazol yellow to the cyanines and isocyanines gives much cleaner plates.

5. 10 ccs. dimethylchinolin ethylate, 1: 300 alcohol, + 10 ccs. ethyl red, 1: 900 alcohol, were added to 1,000 ccs. emulsion. Bathing in aqueous solution gave unsatisfactory results.

6. 50 ccs. glycin red, 1: 600 water, + 80 ccs. thiazol yellow, 1: 600 alcohol, were added to 1,000 ccs. emulsion. The sensitiveness is very strong and even, and increases from the violet to  $\lambda$  475-575, and then gradually becomes weaker.

7. 40 ccs. isocol, 1: 1,000, + 80 ccs. thiazol-yellow, 1: 600 were mixed with 1,000 ccs. emulsion.

This fills up the very striking gap in the blue-green that glycin red alone shows.

The addition of thiazol yellow to ethyl red gave no marked change, and the same occurred with pinacyanol and pinaverdol.

With pinachrome the minimum from  $\lambda$  150-510 was considerably weakened, and the plates were cleaner.

The glycin red+thiazol yellow plates gave much greater density than No. 7.

## MACHINE-PRINTED POSTCARDS.

[The following notes in our contemporary, "The American Printer," are worth perusal for their suggestions of the use made of picture postcards and their mention of the methods found most advisable for their attractive production by American printers. As the photographer is frequently the producer of the subject-matter of the card he should be the one to supply it to the user, though frequently he is so little alive to the possibilities of business that he lets the profit slip into other hands. As regards photo-mechanical cards in monochrome and colour, the photographer is well served by such firms as Messrs. Hood and Co., Ltd., of Middlesbrough, and the London Studio, St. Bride Street, E.C., and he may be advised to look around him for local business in coloured postcards.]

Not only have souvenir postcards been the means of spreading the idea of souvenir postcards with avidity as a most effective advertising medium for familiarising the public with the magnitude of the establishment externally and its beauty internally. He uses them all to illustrate his goods, as advertising "follow-up" cards, etc. Probably the greatest aid to the publishers of these cards is the use of engravings, which any job printer can handle easily and cheaply, and which a photo-engraver can make for him to print in one, three, or four colours from a photograph, drawing or other in one colour. While from some subjects very effective results are obtained by printing in two colours, the most attractive results are those produced by the use of plates for printing four colours. The most practical and economical method of producing these

plates to print in two or more colours is the so-called multi-colour process now in use by the larger engraving houses. In this method a half-tone "key-plate" is made, in a proportionate size, direct from the photograph or other suitable copy (preferably in one colour), and then the required additional plates, whether one, two, or three, as the case may be, are prepared by artists in such a way that when printed with the key-plate the desired picture results.

For ordinary commercial requirements which call for the maximum of effect at a minimum of cost, special attention is devoted to developing the effect of an attractive picture, rather than seeking to portray perfectly and accurately the details of the colouring, although where the work will bear the slight additional expense, the detail can be supplied and a result obtained which compares favourably with higher priced lithographs in six or eight colours.

Printers who have had sad experiences trying to get the perfect register required where all the colour plates are half-tones ("three-colour" and "quadri-colour" work), will find that in the multi-colour process a slight inaccuracy of register will not produce the chameleon or watered silk effect which a similar discrepancy when using all half-tone plates would produce, with a consequent loss of the picture.

"Comics" or humorous subjects are usually produced from special drawings prepared by artists in pen and ink or wash. The key-plate is made from these drawings in line or half-tone. In the cheaper classes of work, in which line key-plates are used, the colour plates are usually made to print flat colours, either solid or a tint.

The cost of the finished cards, like any other printing, depends upon the number of subjects printed at one time and the quantity of same. When a well-equipped printer wants to make up a number of plates in a large form, it is desirable to have the plates backed up with type metal, so that he can use patent blocks to facilitate the make-up and register.

When requesting an estimate for this class of work of an engraver it is best, if possible, to submit the "copies" and state the number of subjects there will be made at one time, the size of proposed plates, and any special instructions regarding alteration, improvement, or modification of copy. The cost of plates then will depend on the condition or kind of copy, the amount of detail in pictures, the grade or finish of work desired, the size of plates, and the number of plates ordered at one time.

It will cost less proportionately per set, if lots of eight subjects

or more are ordered at a time than if each were made separately. The most economical results follow the use of first-class photographic sharp in detail and strong in contrasts, or other suitable copy in colour from which a half-tone or line engraving could be reproduced direct in a proportionate size.

The engraver will deliver the plates, accompanied by a proof of each plate in the colour in which it is to be printed, and additional proofs showing the progressive results as each colour is printed off the other until the finished picture is produced.

In this class of work, as in any other requiring expert knowledge, it is always advisable to confer with the engraver concerning the best means to be used to obtain the required results, and the following up of this practice will do much to discourage the use of photography among printers.

H. A. GATCHEL.

## THE ACTION OF POTASSIUM SALTS ON THE PHOTOGRAPHIC PLATE.

THE view that lead possesses individual activity has obtained considerable support from the experiments of Campbell (1), to whom the greater part of our knowledge of the radio-activity of ordinary substances is due. Nevertheless, great doubt has recently been thrown upon the correctness of this assumption by the later experiments of Elster and Geitel (2), and McLennan (3). The fact that the natural activity of all kinds of lead is not the same is of special interest—in the case of some old samples of lead no special activity could be found—since it cannot be considered consistent with the assumption of an individual radio-activity of lead. The difficulty of coming to a decision in regard to the question has its chief cause in the extremely slight magnitude of the effects to be observed. Practically all observations on the radio-activity of ordinary metals have to be made under these difficult conditions. We have, therefore, thought it well to undertake the following experiments on the activity of potassium in continuation of the facts already published by Wood and Campbell (4), as Wood and Campbell have found ordinary potassium salts possess equal activity per gramme of potassium. As, however, all the potassium salts in commerce come probably from Stassfurt, Wood and Campbell examined, in addition to the commercial products, a sample of potassium sulphate prepared from wood ash, as well as a specimen of potassium feldspar. They found that in the case of the first preparation the activity corresponded with that of the commercial salts, whilst in the case of the feldspar the activity was about 17 per cent. too high. They were able, however, to attribute this discrepancy to a slight percentage of sodium, and confirm previous conclusions that the activity of potassium preparations depended on the potassium. The same assumption in the case of lead has led, as has already been mentioned, to a doubtful result. On this account it appeared advisable to test as many potassium preparations in regard to their activity as possible, and we therefore examined the following:—

- (1) Potash prepared from Molassine meal.
- (2) Potash sulphate prepared from No. 1.
- (3) Potash obtained from Wollsch wire. This preparation can hardly have been produced from Stassfurt.
- (4) Potash sulphate made from No. 3.
- (5) A crude 80 per cent. potash chloride from Stassfurt.
- (6) A pure potash chloride made by repeated crystallisation of No. 5.

RAJAR, LTD., inform us that for the convenience of their customers in London and suburbs they have opened a stockroom at 8A, Red Lion Square, W.C.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Visitors are offered a hearty welcome to the meeting of the London and Provincial on Thursday, June 4, when a paper entitled "An English

- (7) Crude potash sulphate from Stassfurt.
- (8) Commercial pure potash sulphate.
- (9) Commercial pure potash carbonate.

For purposes of trial the following other preparations were used:

- (a) A commercial pure sodium sulphate.
- (b) Lead oxide hydrate of Karlbau.
- (c) Ordinary metallic lead of unknown origin.

In examining the activity of the potassium salts we chose, as the simplest and safest method, the use of photographic plates according to the direction of Wood and Campbell. The plates used by us were those of Hauff, and were 4cm. square. They were wrapped in black paper so that the sensitive film was covered by only one thickness of paper. On this a sheet of brass, 1mm. thick, was laid, and in the middle of this a circular piece of about 1cm. diameter was cut out. On the hole thus made the preparation to be examined was placed, supporting it on a piece of six paper. In the case of the potassium carbonate the plates were placed in a desiccator filled with calcium chloride, in order to prevent absorption of water. At least three tests were made in the case of each material, the substance and the sensitive plates being exposed together in a dark-room for a period of about 120 days. At the end of this time the plates were developed for about a quarter of an hour with a powerful solution of the potassium salts, which gave a circular impression on the plate corresponding to the hole in the sheet of brass. The intensity of the darkening was the same throughout the differences between the plates treated with the same substance were as great as that between the plates on which the different preparations had acted. In the case of sodium sulphate no activity could be found on the plate, not even when treated with uranyl intensifier. In the case of lead hydrate no effect could be seen on development, but on intensification a weak indication of the circular aperture appeared. On the other hand, the metallic lead gave a deposit of practically the same intensity as the potassium salts. In order to give an approximate idea of the intensity of the radiation under examination it may be said that a plate exposed to the action of black oxide of uranium and otherwise treated as above described gave, after five hours, about the same degree of blackening as radiation of the potassium salts and the lead hydrate did in 120 days. This same crude method shows that the potassium salts possess about 1-1000th the density of the  $\beta$  radiation of uranium oxide, a comparison in agreement with the data of Wood and Campbell, who measured the radiation by electrical methods. The darkening caused by metallic lead is to be ascribed to a slight darkening of an individual radio activity of lead, as proved by results obtained with lead oxide.

M. LEVINE.  
R. RUETHEL.

"Journalist in America" is to be read, the author of which is Thomas Bedding, F.R.P.S., who for many years occupied the editorial chair of THE BRITISH JOURNAL OF PHOTOGRAPHY. The meeting will commence at 8 p.m., at the Association's meeting room at the Apple Tree and Mitre, 30, Cursitor Street, Chancery Lane, W.C.

## LECTURES ON PHOTOGRAPHY AT THE ROYAL INSTITUTION.

Optical associations, if nothing else, should certainly induce the members of the Royal Institution to include photography as an occasional subject in their programme of lectures, for was it not at the Royal Institution at the opening of the last century that Davy drew attention to the experiments of Wedgwood, and Sir Wm. Crookes, secretary of the Royal Institution, was an active photographic pioneer in the forties and fifties of the nineteenth century, and editor of photographic periodicals to boot. Therefore in arranging the delivery of a course of those lectures by Dr. Alexander Scott, director of the Davy-Faraday Research Laboratory, the Royal Institution is but maintaining the traditions of a hundred years ago. Dr. Scott delivered the first of his series of lectures on Thursday, May 21. The lecturer began with an historical survey of the work of the pioneers of photography, pointing out that the chemical action of light upon various compounds was known and studied for a long time before photography, properly so-called, became practical. For example, the blackening effect of light upon horn silver was a familiar thing to many early experimenters. Scheele experimented upon the action of light on silver salts, and went so far as to discover that the action was due mainly to the violet rays and not to the red. A notable experiment of Schulze in 1772 was the exposure through a glass of a mixture of chalk and silver nitrate, shaken up together in a bottle. A solution of silver nitrate was used as a secret ink in 1737, and T. Wedgwood, Ritter, and others produced permanent images by similar means upon paper and leather prepared with silver nitrate or silver chloride. The fixing of the images obtained was, however, the stumbling block to all those early experimenters. The first was actually the first to secure a permanent, or fixed, light image in a camera, and this was not produced upon a silver plate but upon bitumen of Judea. If a plate is coated with a thin film of bitumen and partially exposed, the light-struck portions become soluble, while the unexposed parts can readily be dissolved away. Dr. Scott used a solution of bitumen in toluene for coating the plates, and for fixing employed oil of turpentine. The fixing of an exposed image was demonstrated, and it was pointed out that the bitumen process is still in use for photo-mechanical work. A number of experiments to demonstrate the chemical action of light were conducted by the lecturer. The change of yellow phosphorus, and also phosphorus vapour, into the red insoluble form was shown by passing light through a tube, part of which had been exposed whilst the rest was protected by black paper. The deposition of sulphur from a clear solution of sulphur in carbon disulphide was also shown, and the known effect of light upon the conductivity of selenium was demonstrated. The effect of light in promoting the combination of hydrogen and chlorine when exposed to a mercury vapour lamp was also demonstrated. The effect of light was then demonstrated by the white light formed when chlorine peroxide was exposed to light, and the action of mercuric oxalate to the mercurous state was shown in optical lantern. The reduction of ferric chloride and of nitrous acid from a mixture of nitrous acid and alcohol were also practically demonstrated.

To illustrate the action of the ultra-violet rays, a sheet of bromide paper was developed while exposed to a spectrum. The fluorescence of quinine under the ultra-violet rays was shown, and cells of chlorophyll and of permanganate were used to illustrate the selective absorption of various materials.

A solution of nitric oxide and bisulphide of carbon light was shown as an example of a light exceptionally rich in actinic rays.

The lecture concluded with some experiments to show the reactions of ferric and ferrous solutions with ferri-, ferro-, and sulpho-cyanides, and it was pointed out that by taking advantage of these reactions it was possible to develop an image produced by the reducing action of light upon a ferric compound.

A NEW STUDIO IN JAMAICA has been opened by Mr. O. A. Isaacs in Montego Bay.

SOUTHERN SHOWS will be held earlier this year, the dates of the respective exhibitions being: Southampton, October 13-17; Brighton, October 22-26; Southsea, November 2-11.

## Exhibitions.

## THE SCOTTISH NATIONAL EXHIBITION.

Edinburgh is at present in the throes of a national exhibition, and, as it seems proper that such an exhibition should have the hall-mark of royal patronage, it was opened by H.R.H. Prince Arthur of Connaught. At Saughton over forty acres have been utilised for the purpose of the exhibition, which includes all the usual features, including an art section, in which a praiseworthy effort has been made to show the experiment of Scottish art, from Jamieson down to the present day. Included in this building is a small gallery, devoted to photographs, of which the Fine Art Catalogue introduction says: "Photography, the claim of which to rank as an art is so much discussed, has been allotted Room 6, in which a special committee has brought together an interesting collection." But their appreciation of photography evidently does not go so far as to allow it a place in the catalogue further than "Gallery VI.—Photographs," and although the exhibition had been open three weeks on the occasion of our visit no catalogue was available. Failing the publication of a catalogue it might be well to indicate somehow, by small label or otherwise, the title of the picture and the name of the artist. Such an exhibition, given the above-mentioned information, should prove a valuable advertisement to the profession, and it is noticeable that the well-known exhibits are mostly by professionals. What proportion of the unknown work is from their cameras it is impossible to estimate. Much may be learned from the large heads photographed direct by Mrs. Cameron, or from the magnificent collection of the work of D. O. Hill. An exhibit of D. O. Hill's work was shown at the First Scottish Salon at Perth, but it was far short of the present show. It is interesting to note that a painting by D. O. Hill appears in the art section. Wm. Crooke, Edinburgh, convener of the section, has a big exhibit of his well-known portraiture; J. Craig Annan, Glasgow, is also fully represented—"Stirling Castle," "Stoneyhurst College," "Cunninghame Graham," etc., and four Autochromes, the only ones on exhibition; Dan Dunlop, Motherwell, has his Scottish Salon success, "Edinburgh Castle, from Greyfriars," his R.P.S. picture, "The Old Professor," "Anemones," and others; John Moffat, Edinburgh, is represented by "The Dance" and some good portraiture; J. B. Johnston, Edinburgh, by "Beaching the Boat" and others; John Patrick, Edinburgh, by his great portrait of Carlyle, and James Patrick, Edinburgh, by "Evening" and others. J. M. Whitehead, Alva, has a grand exhibit of his quiet, peaceful landscapes, while Drummond Shiels, Edinburgh, is represented by portraiture; Dunn, Aberdeen, shows his charming sketch, "Ella"; while "February," "A Dutch Boat," and others indicate the class of work that G. L. A. Blair, Paisley, is doing. Auld, Edinburgh, shows good work, and the work of R. Dührkoop indicates what is being done elsewhere. The late G. W. Wilson, founder of the Wilsons, of Aberdeen, is represented by the first instantaneous photograph, dated 1856. Amongst others who might be mentioned include A. Keighley, E. T. Holding, Arch. Cochrane, J. McKissack, W. J. Croall, and John Hepburn. Many people will saunter through this exhibition who would never think of entering a photographic exhibition as such; their attention may be arrested and much good may result.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been made between May 11 to 16:—

CINEMATOGRAPHS.—No. 10,167. Improvements in or relating to biograph instruments and the like. Robert Macdonald, 3, Bentinck Terrace, Regent's Park, London.

DEVELOPING.—No. 10,196. Improvements in photographic developing tanks. Allyn Sherrick, Birkbeck Bank Chambers, Southampton Buildings, London.

REPRODUCTIONS.—No. 10,294. Improvements in and relating to photographic reproductions. The Rotary Photographic Co., Ltd., 55, Chancery Lane, London.

**CINEMATOGRAPHS.**—No. 10,396. Improvements relating to an electric apparatus for the synchronous working of a cinematograph with one or more gramophones. Dottor Pietro Pierini, 33, Cannon Street, London.

**PRINTING FRAMES.**—No. 10,421. Improvements in photographers' printing frames. Alfred White, 6, Lord Street, Liverpool.

**DEVELOPING.**—No. 10,437. Improvements in apparatus for developing photographic roll films. James Wyndham Meek, 55, Chancery Lane, London.

**FLASHLIGHT.**—No. 10,440. Apparatus for bringing about the instant ignition of a flashlight powder for photographic purposes. James Patrick O'Hea, 133, Rushey Green, Catford, London.

**CAMERAS.**—No. 10,469. Improvements in reflex cameras. The Thornton-Pickard Manufacturing Co., Ltd., Arthur Gray Pickard, and Thomas William Piercy, 6, Bank Street, Manchester.

**LENSES.**—No. 10,582. Diaphragms for photographic lenses. William Elliott Debenham, 55, Adelaide Road, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**AUTOMATIC FOLDING CAMERAS.**—No. 18,934, 1907. This invention relates to folding cameras of the kind in which the lens-board or panel is automatically advanced upon the base-board when the latter, which is hinged to the camera back, is turned down for use, the object of the invention being to provide mechanism which, whilst automatically advancing the lens-board as above described, yet leaves it free to be advanced still further for focussing purposes without the employment of releasing screws, toothed wheels or the like.

According to the invention, links are provided attached at one end to the usual stays which connect the base-board with the camera back. The other end of each link actuates a short rack on the base-board by means of a slide. A slotted lever, rotatably attached to

Fig. 1.

the base-board, gears with each rack, the slot in the lever engaging a pin on the lens-board. When opening the camera the racks are withdrawn by the stays through the medium of the links, this movement of the racks causing the slotted levers to turn upon their pivots and move out the lens-board. The guide-slot of each lever is open at one end so that on a further displacement of the lens-board the pins with which it is provided are not impeded in any way. In cameras of simple construction, however, and such as are without a double extension bellows, the guide-slots of the levers may be closed, as the lenses of such cameras require but very slight movement on account of their short focus.

In the annexed drawings, Fig. 1 is a side view of the

improved camera. Fig. 2 is a plan of one-half of the same. Fig. 3 is a side view illustrating a modification.

Fig. 2.

$a$  is the camera back connected in the usual way with the base-board  $b$  by means of stays  $c$ .  $e, e$  are the links rotatably attached to the stays  $c$  at  $d$ ; the other ends of the links  $e, e$ , rotate upon pins  $f, f$ , of the slides  $g$  carrying racks  $h$ , guided by means of guide-bars  $i$  on the base-board  $b$ .  $l, l$  are the slotted levers pivoted to brackets  $k, k$  on pins  $m, m$ , fitted on the base-board  $b$ , and provided with toothed segments or wheels  $n, n$ , gearing into racks  $h, h$ . Each toothed segment is provided with a pawl  $p$ , which will ensure the rack gearing into the lever with certain tooth when brought up to the latter.  $p, p$  are the pins on the lens-board, which pins run within the slots of the levers  $l$ . The lens-board is, as usual, rotatably connected with the slide running within the guide-bars  $s$  by means of the hinge  $t$ , and held in a position perpendicular to the base-board with the aid of springs with which the hinge  $t$  is fitted. The guide-bars  $s$  are provided with a catch or the like which automatically locks the lens-board. If required, the extension of the camera may be increased by means of a further guide. The links  $e, e$ , the slides  $g$ , the racks  $h$ , the levers  $l$ , the stays  $c$ , as well as the guides on either side of the camera are arranged symmetrically about the longitudinal axis of the camera.

When folding up the camera, the upper part of the stays  $c$   $h$  to be pressed in the direction of the arrow, Fig. 1, to release the catch or lock notches  $c^1$  therein from the pins  $c^2$  by which

Fig. 5.

they are held in the open position by the springs  $c^3$  at the lower end, bearing against the projection  $c^4$ , and the base-board is then turned up, and thereby the camera closed. The movement of the stays  $c$  causes the links  $e$  to push the racks  $h$  forward, thus imparting a rotating movement to the toothed wheels  $n$ , and simultaneously to the slotted levers  $l$ . The pins  $p$  are thereby compelled to slide along the slots of the said levers and, together with the lens-board, are made to recede into the camera. The same movements take place when opening the camera, but in the reverse order. If the lens-board be moved by hand beyond the normal position, pins  $p$  will escape from the slots of the levers  $l$ , and they will again engage the slots when the lens-board is pushed back.

The arrangement for advancing the lens-board, shown in Fig. 5, differs from that previously described in that the pivots  $m$  of the levers  $l$  are placed further to the front so that the levers are swung from a backwardly inclined to a forwardly inclined position when opening or folding up the camera. Cranley Lancelot Perry, Cheapside, London, for Emil Wünsche, A. G., Reick, Dresden, Germany.

**FOLDING REFLEX CAMERA.**—No. 12,027, 1907. This invention relates to reflex cameras, and has for its object to provide a camera of the class, the body of which, when not required for use, can be collapsed or folded so as to occupy a small space.

To this end, according to my invention, the camera body is constructed as follows—that is to say, there is hinged or otherwise suitably connected, the top, bottom, and ends of the body together so that they can be folded upon one another, the sides also being

arranged so that they can be folded over the bottom. With this construction, when the camera is not required for use, it can be folded or collapsed so that the top, bottom and sides lie in the same plane.

Fig. 1.

Fig. 1 is a longitudinal section of a camera made according to the invention.

Fig. 2 is a section on the line 2-2, Fig. 1.

Fig. 3 is a section on the line 3-3, Fig. 1.

Fig. 4 is a view similar to Fig. 1, but showing the camera body folded, and

Fig. 5 is a section on the line 5-5, Fig. 4.

*a* is the top of the camera, and *b* is the bottom thereof, *c* and *d* being the front and back ends respectively. The end *c* is hinged to the top *a* at *e*, and to the bottom *b* at *f*, whilst the end *d* is hinged to the top *a* at *g*, and to the bottom *b* at *h*, the hinges being so arranged that the body can be folded as shown in Fig. 1 in broken lines.

*i* is one of the sides, the said side being hinged at *i*<sup>1</sup> at its lower end to a narrow strip *i*<sup>2</sup>, itself hinged to the bottom *b* of the camera at *i*<sup>3</sup>. The width of the part *i*<sup>2</sup> is equal to the thickness of the

Fig. 2.

Fig. 3.

bottom *b*, so that the side *i* can be folded underneath the bottom *b* as shown in broken lines in Fig. 3. The other side *j* is hinged at its lower end to a strip *j*<sup>2</sup>, which is itself hinged to the bottom *b* at *j*<sup>3</sup>. The width of the part *j*<sup>2</sup> is equal to the combined thicknesses of the bottom *b* and the side *i*, so that the side *j* can be folded beneath the folded side *i*, as also shown in broken lines in Fig. 3. *k* is the focussing mirror which is hinged at *k*<sup>1</sup> to the end of the camera body, and is connected by a spring *l* to the top *a* of the said body. This mirror is controlled by mechanism not

Fig. 4.

shown in the drawing, and when the camera is folded takes the position shown in Fig. 4.

As will be seen from the drawing the parts which are hinged together are rebated in such a manner that when the camera is extended in the manner shown in Figs. 1, 2, and 3, a light-tight body is obtained. When the camera is not required for use the side *i* is first folded beneath the bottom *b* and the side *j*, then folded beneath the folded side *i* as clearly shown in broken lines in Fig. 3. The ends *c* and *d* are then folded down in the manner indicated in broken lines in Fig. 1, so that the parts assume the position shown in Figs. 4 and 5.

In lieu of constructing the sides *i* and *j* as above described, they may be made of elastic material, or they may be in the form of

Fig. 5.

curtains adapted to be pulled down or rolled up when the camera is to be folded. It will also be understood that the body can be arranged so that it folds from back to front instead of from front to back, as illustrated in the drawing. Paul Ponge, 153, Croydon Road, Anerley, London.

**COLLAPSIBLE LENS HOODS.**—No. 20,706, 1907. This invention relates to means for excluding the unnecessary light which enters a photographic lens during exposure, and provides an adjustable and collapsible shield or hood by which only the actually useful light is admitted.

The shield consists of a collapsible or telescopic set of internally flanged rings, preferably conical, which when extended form a trumpet-shaped hood, a cone or cylinder. When collapsed the rings lie one within the other, occupying a very small space. The end ring, which is either the smallest or the largest, according to the extended shape required, is attached to a plate having a central opening corresponding with the aperture of the lens, and this plate is secured to the lens mount or the camera front so that when the shield is extended the light required for the formation of the image enters the lens unimpeded, but the unnecessary light is cut off by the hood or shield. To secure the hood in extended position the rings may be cut or notched to form spring clips, and their edges channelled so as to spring into engagement as the rings are drawn out. In the accompanying drawings

Fig. 1 is a section of the shield or hood extended;

Fig. 2 a corresponding view showing it collapsed.

Each conical ring *a* is made preferably from thin resilient sheet metal, and is strengthened by the flange *b* at one edge, these flanges also serving to prevent reflection from the internal surface. The ring is cut or notched at *c*, dividing it into a number of spring segments which allow the ring to be slightly expanded and form a spring clip. The rings are provided with the grooves or channels *d* and *e* at the flanged and spring edge respectively, and when the hood is

Fig. 1.

Fig. 2.

expanded, as shown in Fig. 1, the channelled spring edge of the larger cone engages in the other channelled edge of the cone inside,

It will be seen that when extended the flanges *c* reflect outwardly any light which may strike them, and prevent the reflection into the lens which would otherwise occur. To cover the cuts *c* and prevent light entering through them, I provide the small protecting plates *f* fixed at one side of each notch and extending over the other edge. These have the tapering flanges *g*, the inner edge of which is parallel to the axis of the hood, so that the flanges form guides for the ring immediately inside, and prevent looseness of the rings when collapsed.

One of the end rings, in the arrangement shown, the smallest ring *h* I prefer to make of solid metal, and this is attached to a plate having, as mentioned above, an opening corresponding with the aperture of the lens. This plate is screwed or otherwise fixed either to the mount of the lens or to the camera front and the conical rings, extended as shown in the drawings to form either a trumpet or cone, leave a clear cone of rays for the formation of the image, and cut off only such light as would lie outside the image. The means for securing the hood to the camera are not shown, as these may be varied, and are of any ordinary description. The hood may, of course, be wholly or only partially extended as required. It may also be of cylindrical form, but the conical is preferable. Owen Wheeler, "Strathmore," Prince's Road, Weybridge, Surrey, Captain, Reserve of Officers.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Twelve Plates per Minute—A Simple Test.

Referring to the recent method of "two-solution" development, in which the plate is placed first in the developer and next in the alkali, Mr. H. Brenchley (in "The Amateur Photographer and Photographic News" for May 26) writes: "Experiments made at a later date with a two-solution developer of unknown ingredients gave equally good results, so that it would appear the actual developing agents have little influence with the results, provided the solutions are of fair strength."

"The first plate was given thirty seconds in each solution, and the resulting negative is full of detail, but woefully thin, and of no value for printing purposes. Plate No. 2 was allowed one minute in each dish, and is a considerable advance upon the first, but slightly lacking in contrast. The third plate was given one and a half minutes in each solution, and resulted in a good negative of sufficient density and contrast for all-round work, and excellent for enlarging."

"The fourth and last plate was reserved for a little by-experiment. It was first placed in a dish of water for thirty seconds to soften the gelatine, and thus, maybe, allow the No. 1 solution to get to work more quickly. It was then given thirty seconds in each of the two solutions, making a total of one and a half minutes for the whole process, and the resulting negative is almost equal to No. 3 in quality. This seems to show that the preliminary water bath is an advantage, and that the three minutes required to produce a good negative may be considerably reduced."

### Hypo-Alum Toning of P.O.P.

I have had several years' experience with this bath (writes Mr. Harry Carrless, in "Photography and Focus," for May 26), and find that it is better made overnight or twenty-four hours before use, and boiled or distilled water should be employed. Printing should be carried until the shadows are bronzed slightly, toning being continued for rather more than thirty minutes, according to taste.

## New Books.

"The Red Book, 1908-9." Issued by the Affiliation of Photographers Societies.

Dated April, the present issue of the "Red Book" reached on May 25. Its chief contents is, as in previous years, a list of the societies affiliated with the Royal Photographic Society. The number in all 163, an increase of five on the number which appeared as affiliated in the 1907-8 "Red Book." Of the other matters which may be considered specially deserving of attention from honorary secretaries of societies are lists of lectures, prints, and lantern slides available for circulation and the rules approved by a number of judges at "open" exhibitions.

The "Red Book" serves as a permit to photograph in some fifty and twenty places, to which the hospital, town hall, and the churches of Guildford have been added within the past year.

The usefulness of the list of "Places to Photograph" may be seriously questioned. Such a compilation is bound to be "scrappy." A hundred "Red Books" could not contain it were it even approximately complete, and we doubt if anyone would be in the least guided by it in choosing a holiday resort or making an excursion. This, however, is part of the Affiliation's ambitious, but unrealistic "Consular" scheme, under which members of affiliated societies are to apply to "consuls" in other societies when in want of information as to a place they propose to visit. In view of the fact that affiliated societies exist only in 163 places, such a scheme can never attain really useful proportions.

Tables of reference (euphemistically said to be "collated" from various sources) occupy the last portion of the "Red Book." They appear to be accurate, if not original.

## New Apparatus, &c.

**The "Pocka" Tripod.** Sold by Messrs. John J. Griffin and Sons Limited, Kingsway, London, W.C.

A folding metal tripod which packs quite flat for carrying will doubt be appreciated by numbers of tourist photographers, who have learnt, we hope, the very great service which a tripod can as an adjunct to the use of a hand-camera. In the instrument which Messrs. Griffin have sent for our inspection the tripod opens out

a total length of four feet and closes to less than a foot. Despite seven joints it provides a rigid support for a hand-camera of moderate size, and is instantly closed by pressing two buttons in the two upper sheaths of the legs, when the whole apparatus can be reduced to small dimensions of 12 inches by pressure of the points upon ground. We should add that the feet are reversible, one end having a point, the other a rubber shoe for use on polished floors, etc. The price of the tripod is 15s.

**The "Empire" Folding Hand Camera.** Made by W. Watson & Sons, Limited, 315, High Holborn, London, W.C.

In this camera Messrs. Watson have provided the photographer with a portable camera of the hand-stand type of considerably more substantial construction than is usually found in cameras of this class. Moreover, the woodwork of the "Empire" camera is made of well-seasoned materials, with a view to enabling the instrument to withstand severe conditions of climate. The camera in the quarter

size has an extension from the plate to the diaphragm of the lens of ten inches, and possesses great rise of front and a cross movement of over 1½ inches. It is built the upright way of the plate, being turned on its side for landscape exposures. A

versible finder (two levels) and a convenient focussing scale are features of the instrument, which, with R.R. lens of Messrs. Watson's manufacture fitted in a Bausch and Lomb shutter, costs £10s. complete with three dark-slides, or the camera may be obtained with a "Holistigmat" Series I, *f*/6, for 12 guineas, in which case focussing scales are fitted for the three foci—5½, 8½, and 12 inches—provided by the latter lens. For a light and efficient camera we can recommend this new instrument of Messrs. Watson's. External measurements, when the camera is closed for carrying, are 6 by 4½ by 2½ inches.

"Imperial" triple-expansion two-shutter outfit. Made by the Thornton-Pickard Manufacturing Co., Ltd., Altrincham.

In the 1908 model of this stand camera the Thornton-Pickard Co. have made improvements which give a still further range of movements to the camera and fit it still more for all descriptions of photography. The chief item is in respect to the focal-plane shutter, which is now made with two slits, the use of one or other of which, in conjunction with the series of five tensions of the actuating spring, gives a series of exposures from 1-25th to 1-1000th of a second. The change from one slit to another is very conveniently made, and the

also automatically opens itself to full aperture for focussing. The adjustments are made from the outside of the camera, and the facility which the possessor of this apparatus thus has in photographing the most rapidly moving objects makes the apparatus of general application. In other respects the camera is an improvement on last year's model, particularly in the front, which works freely in brass struts and gives a very great rising movement of the plate. The camera has the necessary wide-angle movements and a maximum extension of 22 inches, is fitted with swing-back, rotating

turntable, and, like other manufactures of the Thornton-Pickard Co., is produced with a regard for convenience and rapidity in use. The price of the apparatus in the half-plate size, complete with focal-plane and Thornton-Pickard roller-blind shutters, tripod, one double dark-slide, and Beck lens is £25 10s.

### CATALOGUES AND TRADE NOTICES.

"THE PROFESSIONAL PHOTOGRAPHER."—The May issue of this monthly journal contains some interesting notes on cathedral photography with a roll-film camera and on new apparatus for tank development more particularly useful to professionals. As usual, "The Professional Photographer" is well illustrated and produced.

THE CITY SALE AND EXCHANGE, of 81, Aldersgate Street, E.C., are issuing a list of second-hand goods, including cameras, lenses, enlargers, etc., which they are offering at considerably reduced prices. The list may be obtained on application to the above address, where also the goods can be inspected.

THE WESTMINSTER PHOTOGRAPHIC EXCHANGE, LTD., have just published the third edition of their list of second-hand and shop-soiled photographic apparatus, which includes various types of cameras (hand and stand), lenses by well-known makers, shutters, and a large variety of accessories. The list may be obtained on application to the above firm, at 119, Victoria Street, London, S.W.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, MAY 30.

Southend-on-Sea Photographic Society. Outing to Canewdon.  
Chelsea and District Photographic Society. Excursion to Ewell and Chessington.  
Liverpool Amateur Photographic Association. Excursion to Bamford.  
Handsworth Photographic Society. Excursion to Forge Mills for Coleshill.  
Southampton Camera Club. Outing to Hamble and the Marshes.  
United Stereoscopic Society. Outing to the Vale of Middlesex.  
South Suburban Photographic Society. Excursion to Holmwood and Dorking.

Tunbridge Wells Amateur Photographic Association. Open Night.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, May 26, the president (Mr. J. C. S. Mummery) in the chair.

Mr. Thomas Manly gave a demonstration of the new method of working ozobrome, described last week in "The British Journal of Photography," and consisting in the use of a weak acid bath in place of water for the preliminary soaking of the pigment tissue. Mr. Manly showed the control in the contrast of the print which was possible by longer or shorter immersion of the tissue. In the short discussion which followed Mr. A. H. Blake spoke of the facility of the ozobrome process for controlling the values of a print. He preferred the No. 1 method for this purpose, and exercised control with a brush or the finger either when the print was being developed in the hot water, next while it was lying in cold water, and finally while it was half dry. He found it necessary at the first of these three stages to keep the print just below the surface of the hot water. If removed from the water reticulation was apt to occur, whilst if the print was deeply immersed it was difficult to use the brush or finger with sufficient delicacy. Mr. Blake, however, admitted the great waste of prints in carrying out such control

work as this, and instanced a case which had recently come to his notice where fire had broken out in the house of a worker in the gum-bichromate process owing to the great accumulation of waste prints on the householder's table. A hearty vote of thanks to Mr. Manly concluded the meeting.

**THE PHOTOGRAPHIC CLUB.**—At the meeting on Wednesday, May 20, Mr. W. F. Slater, F.R.P.S., delivered a lecture on the theory and practice of time development, having particular reference to the Kodak developing tank for roll films. In the course of an interesting paper Mr. Slater enunciated the principle that in the case of properly exposed plates the correct stage of development was more accurately arrived at by the use of a standard developing solution at a standard temperature and applied for a given time than by the usual method of relying upon judgment and ocular inspection. He further contended that in cases of over- or under-exposure better results were obtained by treating the plates precisely as though they were correctly exposed than by attempting any modified treatment to suit the particular case. From the discussion that followed it seemed to be the opinion that, while the system recommended was useful under some circumstances, and was perhaps the safest for beginners to follow, there was an amount of control that could be usefully exercised by the expert photographer.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At the meeting held on Thursday, May 21, Mr. A. Haddon in the chair, Mr. Frank Donisthorpe demonstrated the new Donisthorpe process. He pointed out that the negatives for this process should be thin and free from fog, and said that the hardening bath used acted as a strong intensifier. A lively discussion was carried on during the demonstration. The chairman elicited that the process had been tested for permanency by a print being exposed to the full light for nine months, half of which was covered, and that no change could be detected; also that the dyes could be removed from the negatives by washing, and placing it in a special converting solution which brought it back to its original state.

In reply to Mr. Teape, the lecturer stated that the only way to use a negative of ordinary density was to reduce and re-develop it before it was put into the hardening bath, otherwise the resulting print would be hard and contrasty. In reply to a question as to the reason of the tinted skies in the prints made in the room, the lecturer said that this tint only showed in the first pulls, and then not on every occasion.

As to the number of prints it was possible to obtain from a negative, the lecturer said that he had never come to the stage where the negative had worn through, and it was an easy matter to get off fifty or more.

## Commercial & Legal Intelligence.

**A CASE OF ASSAULT.**—In the Belfast Recorder's Court last week William Wilkes, photographer, 79, Divis Street, sued Henry Ingleby and David Keell, 63A, North Street, photographers, to recover £50, loss and damage sustained by the plaintiff for that the defendants assaulted, beat, and ill-treated him, whereby the plaintiff sustained serious injuries.

Mr. T. J. Campbell (instructed by Mr. John Graham) was for the plaintiff, and Mr. M. G. Ellison (instructed by Mr. Thomas Barkley) represented the defendants.

In stating the case Mr. Campbell said some time ago the plaintiff was in the employment of the defendants, and since he had left they had molested him, threatened him, and actually gone to his new employer and tried to get him dismissed. The conduct of the defendants all along had been of a very high-handed character, and on April 4 they committed a brutal and dastardly assault on the plaintiff. On that occasion his client was going home, about half-past ten, in company with a lady friend, to whom he had been paying attention. On the way up Clifton Street he noticed one of the emissaries of the defendants, who were apparently watching for him. As the plaintiff was standing speaking to the young lady at her door the defendants rushed up and one of them dealt the plaintiff a blow on the head. The other defendant closed in, and the two men proceeded to belabour his client in a most brutal fashion. There

was a wound on his arm, which must have been inflicted by some implement, while his forehead and chin were also bruised. As a consequence of the treatment he received from the defendants the plaintiff had to attend two doctors, who would tell the jury as to the extent of the injuries. Those were the facts of the case, and he asked the jury to teach the defendants that they could not resort to a midnight attack to deal with a man who was in commercial competition with them in the city.

Mr. Ellison, for the defence, said the case he had to tell the jury was less romantic than that told by Mr. Campbell about assassins coming at midnight and assaulting the plaintiff. On April 3 plaintiff was dismissed by the defendants. Miss Jennings, whom the jury had heard about, was the defendants' bookkeeper, and as such kept the keys of the premises, and on the night in question the defendants visited her house for the purpose of getting these keys. They found Miss Jennings standing outside the house with the plaintiff. Mr. Keell asked the young lady to speak to him, and when she refused about to do so the plaintiff said to her, "Stay where you are." The plaintiff then caught Keell by the coat, and the three men had some little argument. There was no real fight, and no weapons used. He submitted that whatever row there was was caused by the plaintiff's bad temper.

His Honour, in summing up, said if the jury believed the story told by the plaintiff, then it was not a case for nominal damages. If the plaintiff was telling the truth it was a deliberate attempt on the part of the defendants to put him out of business. It was a dastardly affair, and he was glad to say it was not the English way of doing business.

The jury found for the plaintiff, and assessed damages at £40.

**AN ENLARGEMENT CASE.**—At Chorley County Court, before Judge Hamilton, Samuel Cohen, trading as the Bona-Fide Art Company, Hightown, Manchester, sued Mrs. M. E. Ashton, landlady of the Wheatsheaf Hotel, Atherton, for 16s. 6d. in respect of the fraudulent enlargement of her daughter's photograph supplied to the plaintiff by the defendant. Verdict was given for the defendant.

**THE STORY OF A BOND STREET BUSINESS.**—The public examination took place at the London Bankruptcy Court on May 21 of Richard Berwick Hope, photographer, of 154, Portsdown Road, Paddington, and 171, New Bond Street. Debtor returned his liabilities £5,568, of which £4,689 is expected to rank for dividend. There are no assets. In reply to questions the debtor said he was formerly in the army, resigning in September, 1898, with the rank of lieutenant. In 1899 he purchased for £2,650 a half share in the business of a photographer and miniature painter, carried on at 175, New Bond Street, W., and afterwards removed to 171, New Bond Street. The purchase money debtor borrowed £2,000 from his wife. Branches were opened at Brighton, Liverpool, Manchester, and Brixton, and the debtor provided £600 further capital for this purpose. In 1901 the business was sold to a limited liability company, the bankruptcy share of the consideration being £6,167, of which 1,061 was paid in cash, out of which he subscribed for 500 shares, and the balance in fully-paid shares. The debtor was appointed joint managing director, at £150 a year, and he held the office until August, 1907, when the company went into liquidation. In November, 1905, the debtor and his brother purchased the London business of the company from the Receiver for the debenture holders for £1,250, and carried it on successfully at 171, New Bond Street until March 1907. Then further capital being required they sold the business for £5,500 in fully-paid shares to another company, formed to take it over. The debtor received 2,000 shares and sold 500 of them immediately afterwards for £500. This money was used in paying partnership liabilities. The other 1,500 shares were deposited as security for a loan with a moneylender, who recently disposed of the shares for £62 10s. to another creditor, who held a second charge on them. The debtor was appointed a director at £200 a year, and subsequently managing director at £350. This post he resigned. In June, 1907, debtor was appointed managing director at £100 a year of a small company formed to exploit the patent rights in a ladies' dress clip. Debtor sold a portion of his interest in this company to another person for £500, and also received 600 fully-paid shares from the company. The company is not now carrying on business. The debtor attributed this insolvency to the failure of the last-mentioned company, to the fact that the photographic business had been carried on at a loss since March, 1907, and to depreciation of

the shares in the photographic company. The examination included.

**BRECAMBE BANKRUPTCY.**—A dividend is to be paid in the estate of Alfred Ernest Edward Clay Poole, photographer, the Crescent, and Midland Studio, Northumberland Street, Mbe, Lancs. Claims should be sent by June 5 to the Official r, Preston.

**IAN KODAK COMPANY, OF NEW JERSEY.**—The usual quarterly ls of 1½ per cent. (being at the rate of 6 per cent. per annum) e outstanding Preferred Stock, and of 2½ per cent. (being at of 10 per cent. per annum) upon the outstanding Common t the Eastman Kodak Company, of New Jersey, will be paid 1, 1908, to stockholders of record on May 29, 1908.

#### NEW COMPANIES.

**ORD, LTD.**—Registered May 13. Capital £1,000, in £1 shares " and 500 "B"). Objects: To acquire the business of a turer of, and dealer in, photographic plates, paper, and s carried on by W. de Welford, at 61, Mansfield Row, Ilford. al public issue. Registered office, Wharf House, 4, High ford Hill, Essex.

## Correspondence.

*Correspondents should never write on both sides of the paper. Notice is taken of communications unless the names and addresses of the writers are given.*

*We do not undertake responsibility for the opinions expressed by correspondents.*

#### SUNDAY LABOUR.

To the Editors.

men,—In reply to your correspondent, "Six Days," I can that last season I was fined 10s. 6d. each week for Sunday and each week I employed a solicitor, and shall do exactly thing again all this season, commencing on Whit Sunday, at place. The takings average more or less, according to the of trips which are run to the place, and as at Cleethorpes e a great many more trips on a Sunday than on most of er days, I take as much money on a Sunday as on any three week days combined. There is a vast difference a football match and having your photograph taken. People ules to see a football match, whereas, when you have people in your shop window at photos shown, it often takes a al of persuasion and coaxing to get them in to be photo- and if the photographer did not take these Sunday trippers ple would be home again the same evening, and he would sed all that money for ever. If Sunday trading is to be let those in authority commence by closing public-houses, trams, trains, and all kinds of Sunday labour. Look, for at the various callings followed, say, in Whitechapel and etticoat Lane, on a Sunday. If your correspondent has to en days and does not like it, let him get another situation, will only have to work six days, or start a business on his unt. What is the good of running excursionists into a place day if they cannot be catered for? They come for a day's ut—perhaps the only one they get for the year—and they ir photographs taken. They want something to eat, and hopkeeper in Cleethorpes sells a penny banana or a penny- sweets, or a pipe of tobacco, or takes a portrait on a Sunday s it on a Monday he is summoned, and is fined 5s. and der an old Act, Charles II., 1677, made before photography invented or thought of. Therefore, I contend it was never r photographers at all. Let me conclude by saying that, in on, any man who would shut up a photographic studio and ublic-house open deserves three months, without the option —Yours,  
r Light Studios, Promenade, Cleethorpes. JOHN HAWKEY.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

E. D. D. Terry, 164, Upper Richmond Road, Putney. Photograph of a Group of Gipsies Round Two Pots Over a Camp Fire.

ED. PLOWMAN.—Stand cameras are not permitted at all. Hand-cameras, so we are informed, may be used by amateurs on a permit being obtained from the offices of the exhibition.

J. C. COUCHE.—Your query is one that we cannot give a decided opinion upon, as we have not seen the agreement you made with regard to allowing the part of the money to remain for the three months. The matter, it seems to us, from the small data you give, to be somewhat complicated, and we should therefore suggest that you consult a solicitor, and put the thing in his hands to deal with. Anyhow, we do not think it will be wise for you to act as you suggest without first consulting your solicitor.

**COPYRIGHT QUERY.**—I have bought a very large (36 x 18) and valuable negative. Nothing has been said about copyright. The negative was taken forty years ago. I want to protect my prints that I take from the said negative. Can I do so, and what is the best method? Your advice will be gladly accepted.—F. HOLLOWAY.

You should have ascertained about the copyright when buying the negative. There may be a copyright in it, and if that is the case it will be illegal for you to produce prints from it. If there is no copyright in it, and probably that is so, as it has been taken so long, you cannot claim a copyright in it. If there were any copyright in the picture, as the negative was sold without it being assigned, the copyright in it has expired and any one can copy it.

**POSTCARD PRINTING.**—I should be extremely obliged for your opinion on the following questions:—I am installing in my work-room a bromide printing machine, which prints a large sheet of card bromide for postcards, about 24 x 22, or about twenty-eight postcards, and what I wish your opinion on is about printing on the reverse side. I am not wishful to go to a big expense in having a proper printing machine, I think of trying to print them on a mangle with very good rollers and printer's blanketing put on them. Do you think this ought to do all right for this, and is it advisable to get a litho printing surface, half tone or typo? I am afraid with typo it will make too much impression on the photographic side of the card. Trusting this is quite clear.—ANXIOUS.

This is a query we cannot answer definitely as we have had no experience in the use of a mangle in printing, either lithographically or typographically. We should advise you to make some experiments in the way you propose and see how it answers. We should think that, probably, the best thing for you to do would be to get a lithographer to do the printing on the reverse side of the sheets for you. It would, probably, taking time into consideration, cost you less, and the result would be better than you could obtain by the primitive method you propose.

**LENS NOT WORKING TO FOCUS.**—I have just got a half-plate lens, rather cheap one, no name on it. In focussing, I get the figure sharp on ground glass at full aperture, which is f/8. I stop down to f/11 for head vignette, and it looks perfectly clear and very sharp, but when I develop plates I find the face is not sharp. At first I thought it was because the ground glass was not just where the plate came, but I find on measuring it is exactly true.

Also, to test it, I tried another lens on camera which I knew was a good lens, and I got a good sharp negative. The thing that puzzles me with this lens is why the figure appears sharp on ground glass and out of focus on negative. I have just tried eight plates on different sitters, and focussed by three of us, but all had the same result—the coats and dresses appearing fairly sharp, but the faces out of focus. Can you enlighten me as to the cause?—PUZZLED.

Your lens is evidently not achromatic—that is, it is not corrected for colour. Try racking in the camera slightly, after focussing and before exposing. A few trials will show whether this is the true cause of the trouble, and also the amount of racking is required to correct it.

W. E. L.—The publication is "Photographische Korrespondenz," published at 12, Backerstrasse, Vienna. No doubt you can obtain the issue of the journal from this address or peruse it yourself in the library of the Patent Office, Southampton Buildings, London, W.C., or in that of the R.P.S., 66, Russell Square, W.C.

X-RAY PHOTOGRAPHY.—I have recently developed several X-ray 12 x 10 plates for a local doctor. Some came out very thin, some seem to fog quickly, and the results, taken as a whole, are not as good as I should like to produce. The doctor places the plates under the patient, and sometimes they get broken by the patient's weight. Please tell me in your valuable journal: (1) Which is the best brand of plates for X-ray work? (2) What exposure ought the doctor to give? (3) Which is the best mode of development? and (4) Ought the developer to take as long as for other ordinary work, or longer?—J. H.

(1) There is a great difference of opinion as to the best plate for X-ray work. Some favour a slow and some a fast plate. Plates made by Lumière, B. J. Edwards and Co., Ilford Ltd., and Sanger-Shepherd are largely in use. (2) Impossible to say. It varies with the thickness of the part of the body which is being photographed. (3) The ordinary one. (4) As usual.

LUXEPIA PAPER.—In your review of May 1 of "Luxepia" you state that some 40 seconds to daylight was needed. I have experimented with an average negative and found that three to five minutes was not enough, and that although the image was "printed out" a pale brown, development had no greater effect. The Watkins act (standard meter) light was 60 seconds to the same light. My chemicals were all fresh, with the exception of the potass citrate, which had liquefied to treacle consistency, but that should not make any difference. Can you help me?—S. H. C. (St. Ives).

We can only repeat that the exposures mentioned were those actually given to negatives in rather dull afternoon light. The image should not print out. Apparently your failure is due to reversal by over-exposure. Try with the lesser time of exposure.

TONING BATH.—Would you please let me know what I ought to do in the following? I am using the following bath for toning:—(A) 15 grains chloride of gold, 7½ oz. of water; (B) 1 oz. ammonium sulphocyanide, 16 oz. water, taking 1 oz. of each to 15 oz. of water for use. Ought I to throw this bath away when done, or can I add a quantity of each A and B to it, and throwing the bottom part in the bottle away when using again?—CYMRO.

The bath can be further strengthened by adding A and B, but it does not keep in its best condition long after doctoring in this way.

DETECTIVE.—We are afraid we can only suggest that you inquire of the police, who, if you have any clue, can perhaps assist you. We doubt if one of the detective agencies, whose announcements you will see on the back page of the "Daily Telegraph," could do much. It depends on what clue you have.

RETOUCHING (reply to E. W.).—The children's faces are excellently worked, and display a very good knowledge of retouching indeed. The large head is rather undecided in the grain and modelling, but is soft in effect. One of your best points is careful retention of the likeness. All the high-lights should be worked up on the woman's face, and, considering the freckled nature of the sitter, a bolder skin texture should be shown. There is not much to find fault with that could not be easily remedied with a little extra attention.

O. A. ISAACS (Jamaica).—Thanks for your letter. Prints by the new process are indistinguishable from those by the usual method. Those by the second method you name are not quite equal. As regards the other two, the materials are not yet on the market

here, but our own experience of the development paper to prophesy a wide use for it.

RE-CEMENTING LENSES.—I have an old portrait lens, and should clean it myself. Can you tell me how to separate the c lenses and how to join them together again with fresh balsam?—W. CREASEY.

Unless the balsam is very badly discoloured, or the glass separating, we should not advise you to tamper with it, as a rule novices' attempts at re-cementing lenses are great successes. However, this is how the work is done: the lens in a saucepan of cold water and gradually heat it till the glasses can be slid apart with light pressure. Next clean the old balsam with turpentine. Then make the glass, place a drop of Canada balsam in the centre, and press surfaces in contact so as to squeeze out all the balsam. Finally, put the lens in a place where it can be kept warm till the balsam has hardened. This will take a rather long time.

OTHELLO.—The American Express Company, Waterloo Road, S.W., will take parcels carriage forward.

INTERESTED.—Apply to Messrs. Newton and Co., 3, Fleet Street, London, E.C. They are one of the few firms making apparatus.

X.Y.Z. AND OTHERS.—In our next.

J. OSBORNE.—Out of our province. You should apply to an expert, such as Mr. A. Rischgitz, The Studios, Linden Road, Bayswater, W.

PIGMENT PAPER.—Please give me a formula for coating a paper with a mixture of fish glue and gum or some other colloids, so that pigment or pigments which will work in the same way as the commercial "gum" papers—the paper so coated being subsequently sensitised as may be desired.—ENQUIRER.

Makers of commercial papers do not publish the formulae for their emulsion. You might, however, try some such mixture as follows: three parts of a solution of gum arabic 1:8 and one part glue; to this add a small quantity of pigment the colour desired—very little is required. A few tentative experiments will show you the best proportions to employ for your purposes.

HIS HOLINESS THE POPE AND URBANORA.—The news will be welcomed by good Catholics all over the world, and, indeed, who recognise the educational scope of "Urbanora," that His Holiness the Pope has during the week entertained a party of Mr. Urban's expert bioscopists at the Vatican and sanctioned the showing of a delightful intimate series of animated pictures to the Pope and his suite. The visit to Rome was undertaken at the express desire of the Pope, and as facilities of a quite unusual character have been afforded the operators, the most entertaining results may be anticipated. In the meantime Mr. Urban will show his pictures at the Alhambra, on and after Monday next, the veritable record of the hunt in Russia—the pursuit of a huge black brute by a multitude armed with axes, pitchforks, bludgeons, and, last of all, firearms. In no sense is this a "faked" or an improvised film, but an actual battue, only successfully photographed after many and at obvious risks to the man behind the camera.

\* \* \* NOTICE TO ADVERTISERS.—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

lton Grundy gives a description and drawing of an attach-  
vised by him for converting an ordinary camera into a  
(P. 431.)

Obscure points in the ownership of negatives are raised by a  
dressed to us this week. (P. 430.)

ittings among the humble *midinettes* of Paris are reported in  
paper. (P. 429.)

man line of steamships is said to be contemplating the  
of photographic studios on board the vessels. (P. 430.)

toning process, arc lamps, and other apparatus are among  
of the week. (P. 435.)

printer has been recently recommended to pigment with  
ect before him. (P. 430.)

rospectus of the Royal Photographic Society's exhibition  
been published. We give an abstract of the chief regula-  
p. 434.

ranco-British Exhibition.—We give particulars of photo-  
exhibits at present discoverable in the exhibition. (P. 434.)

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

hibition of the Society of Colour Photographers is open daily  
ellington Street, from 10 a.m. to 8 p.m. (Saturdays, 10 to 5).  
hibition will be open on Monday next (Whit Monday) from  
to 8 p.m.

view of the exhibits by Mr. E. J. Wall appears on p. 41.  
E. H. Rawlins recommends persulphate as the reversing  
for Autochrome plates. (P. 43.)

Lumière and Seyewetz have given further directions for  
g (during development) for errors of exposure. (P. 44.)

acements of still other screen-plate processes continue to be  
P. 45.)

ch worker who has recently made 1,300 Autochromes in  
East has explained how he practises development, etc., en  
P. 46.)

ondence on colour photography deals with Autochrome  
landscape and on tour, and with the use of leuco dyes for  
duction of Autochromes. (P. 47.)

## EX CATHEDRA.

### The R.P.S. Exhibition.

The prospectus of the forthcoming ex-  
hibition of the Royal Photographic  
Society has been issued, and is obtainable from the secre-  
tary at 66, Russell Square, London, W.C. With the ex-  
ception that a sub-section (IIa.) of the technical class has  
been created for screen-plate colour transparencies, no  
alteration in the general scheme of the exhibition has been  
made. We wish we could say that it had. The exhibition  
authorities at Russell Square have no doubt considered  
the revision of the regulation as to Section III., which  
includes professional photography, but they have made  
no change in the regulations which, during the past year  
or two, have failed to attract professional work. Mr.  
Crooke has loyally supported the exhibition with his  
magnificent portraiture, but other leading workers have  
been content to offer their work for inclusion with that  
of anybody who cares to pay for space at 5s. per foot run.  
We are not surprised that under these circumstances a  
representative show of professional work has been missing  
from the Royal for the last few years. The professional  
photographer has naturally to look to the company he  
keeps, and if he cannot afford to purchase space sufficient  
to set him apart, he is naturally reluctant to exhibit under  
conditions which suggest that he has been classed by the  
Royal Photographic Society with anybody who pays for  
space alongside him.

\* \* \*

### The Photo-graph as County-court Evidence.

We were interested in hearing, a little  
time ago, of a photographer in a  
Northern suburb, who, in suing for pay-  
ment of an account, produced a  
photograph of the defendant of the suit in proof of  
the latter's ability to pay the money. He won his  
case, and now we see that a photographic firm in  
the South-West of London has gone one better in taking  
out a summons against a person who owed them  
£5 9s. 6d. The person said he was a butcher, but had  
done nothing for a long time. The plaintiffs' representa-  
tive stated that their recalcitrant customer was a com-  
mission agent as well as a butcher, and that not long ago  
he had provided a very swagger wedding on the occasion of  
his daughter's marriage. A photograph of the wedding  
group was handed up to his Honour, who made an order  
for the payment of the money.

\* \* \*

### Cela ne s'engage rien.

If we may believe a Paris daily paper,  
the latest outbreak of the "free" sitting  
is now taking place in Paris.  
"Cherchez la femme" has long been the keynote of many  
a dramatic plot, just as it will always be a good motto for  
photographers; but a new significance has been given to

it by the tactics of photographers in the French capital, who are making a bold bid for the patronage of the *midinettes*, pretty and otherwise, who throng certain quarters of Paris during the hour allowed them for their frugal lunch. The dressmaker's "improver," and even the factory hand, is a daintier little person than her London prototype, and perhaps a little more susceptible to the overtures of the pavement photographer. At any rate, we learn that the latter finds many sitters for a series of portraits in six different positions, which he offers to take on the chance of Mademoiselle choosing to buy them when she sees them the next day. "*Cela ne s'engage rien*" is the motto of this newest apostle of the "free" sitting, and to the accompaniment of a good deal of fun he photographs his sitters *en plein air*. The next day he brings the portraits—all six positions—and Mademoiselle usually purchases and orders some further copies. All of which makes us wonder whether we shall run across the same sort of thing in Wigmore Street or Soho Square, to name two thoroughfares where girl employees are numerous; or will the police mercifully veto this form of ex-studio portraiture?

\* \* \*

### The Studio Aboard Ship.

We learn from a German source that a photographic studio has been fitted up on the American liner of the North German Lloyd, the "*Kronprinzessin Cäcilie*." The studio is to provide every facility for photographic portraiture, and the ship's photographer will complete and deliver copies to the traveller's order. The studio will also undertake the developing and printing of amateurs' exposures made *en voyage*. It can certainly be no particularly consoling sight to see photographic business spirited away on to the high seas, but we have no information as to whether the productions of the floating studio are to compare with those of a well-equipped establishment ashore; but the incident may serve to provide a hint to photographers of the unlikely places where openings are to be found for photographic business. It may be seriously questioned, though, whether many people feel that they are looking their best during an Atlantic passage in not the best of weather.

\* \* \*

### Elementary Optics Again.

Some time ago we had occasion to comment on some extraordinary lens tests described in an American magazine, and the author of these tests now admits that our criticism was justified in one case, though in the other cases he calls upon various authorities to prove that we were altogether in the wrong. We objected to the test given for flare spot, as it was merely a test for the erect image sometimes formed on one side of a plate when a bright light is sharply focussed on the other side. This is not the effect commonly known as flare spot, which is sometimes described as an image of the diaphragm, but which, more correctly, is a much out-of-focus small scale inverted image of the view in front of the lens. The image to which flare spot is due is generally formed close to the lens, that causing the other effect, very close to the plate, and the two effects are quite different. Very curiously our American writer remarks in regard to his own test: "I am told it is the test for ghost or false image." We did not tell him this in our note, but it is quite correct, and we are glad to see that some one else has backed us up in our attempt to put him right. He quotes an English authority in support of his own method of testing for chromatic aberration, but if he will refer again to the authority in question he will find some very essential differences. The test chart is placed at an angle with the lens and focus is secured in the centre, but there is nothing

about putting the chart at an angle in the tests we cited. Other items in our note being passed over, we may assume that the writer is unprepared to defend strange ideas with regard to covering angle and distortion.

\* \* \*

### 'Oil' and Nature.

From all account the oil process and its allied method, "bromoil," are obsessions of the present season among photographers whose aims are the exhibition walls of the Royal, or Northern. Most people will be surprised if "oil" not come out far away at the head of the pictorial parade in Pall Mall and the New Gallery, while as for the Northern, not the stalwart Inston plumped for it without qualification. We hear of exhibitors whose pictures have not been seen in late years taking up their work under the inspiration of "oil." Amid all that is being said and written on the subject, we come across one little suggestion in the "Secret Letter" of the Scottish Photographic Affiliation, which is worth emphasising. There a Mr. Peter Mitchell anticipates that the "oil" worker will practise the profession with his subject before him. We sincerely hope he is right—there seems no good reason why he should not. We shall then expect to be spared some of the extravagancies of Nature of which the oil process in incautious hands is likely to prove so fruitful. Delightful visits to the immediate future—the photographer seated in a village street, before his bromoil enlargement, is pigmenting!

### A DIFFICULT POINT IN THE OWNERSHIP OF NEGATIVES.

A QUERY of more than passing interest to professional portraitists, and their customers, reaches us this week. The principal interest in it is that it involves some points with regard to the ownership of negatives and the disposal of them. So far as the Copyright Act is concerned there is no provision in it which seems to meet the present case; neither does anything that has been legally decided with reference to the ownership of negatives bear directly on the point. It has, over and over again, been decided in the Courts that negatives taken in the ordinary course of business are the property of the photographer who takes them. It was also decided, some twenty years or so in the case of Pollard versus the Photographic Company, that although the photographer is the owner of the negative, he has no right to use it for any purposes of his own—such as producing prints from it for sale, or making enlargements for the purpose of specimens.

It is perfectly clear that, as the photographer has no right to make copies, he has no right to sell the negative itself. But supposing the photographer becomes bankrupt, then the whole of his property passes into the hands of the Bankruptcy Court, which then disposes of it for the benefit of the creditors. All the belongings, the stock, the trade, apparatus, negatives, etc., are sold for what they will fetch. In the case of the purchaser of the negative there seems to be, so far as the law is concerned, no restriction as to what he may, or may not, do with them. If he has passed legally from the possession of the one who once owned them to another who, by purchase without restrictions, becomes the possessor of them. We here mention that some few years ago, at the Fine Art market at Islington, we saw displayed for sale a number of fine carbon enlargements, expensively finished, together with several piles of negatives. We recognised the production of a then well-known West-End firm, and had "come to grief" some little time previously. Looking at some of the negatives, we saw on them the names of several fashionable and titled folk. It occurred to us at the time that, according to law, there was no

vent the negatives being used for specimen purposes, to the annoyance of the sitters. The case stated by respondent is precisely on all fours with this, and clearly put, we here give his letter in its entirety:

"I would esteem it a favour if you will kindly give me information on the following points:—A, a photographer, being in bankruptcy, trustee of the estates, sells to C, a local stationer, all the negatives, belonging to A, of his private customers. C, having bought the negatives, decides to sell the negatives to children and general public at a halfpenny each, but refuses to supply any one negative of a particular individual. X Y Z, having had several photographs taken by A, is desirous to prevent the indiscriminate sale of negatives of himself and family, and desires them to be either destroyed or sold to him. The stationer says he cannot attempt to destroy amongst thousands of negatives for them, as they have all been sold up, and, moreover, he wouldn't know them if he saw the negatives. What action can X Y Z take to prevent their sale, and against whom should he proceed, as having paid for the photographs, he understands that, whilst the negative was in the photographer's possession, the sole right of the use of same was his?"

"I am not at all to be wondered at that 'X Y Z' feels annoyed at the negatives of himself and his family being dealt with in this way. But the question is, what can he do, or can he do anything, to prevent the negatives (purchased by him) from coming into the possession of the stationer in a perfectly legitimate way, and it would be a hardship upon him if he could not dispose of them in the way he is doing. At the same time one must have some sympathy with 'X Y Z' in his knowledge that portraits of himself and members of his family are being so sold without his knowing to what uses they may ultimately be put, and what annoyance it may possibly cause him. If any remedy is caused he has no remedy against the photographer, as he is no party to it, as the negatives were taken from him according to the law of bankruptcy. He did not voluntarily part with them, and we do not see that any action could lie against the present owner of them."

Should the negatives be used for any improper purpose it is possible that an injunction from the Court of Chancery to restrain might be obtained to stop the annoyance, but that would be a somewhat costly proceeding, even if successful. In that case action would have to be taken against those who are actually making the improper use of the portraits, as an action could not be sustained against the photographer who originally took the negatives. Nor would one lie against the trustee in the bankruptcy proceedings, nor, we imagine, against the stationer. It is very probable that the latter, as a matter of business, would sell the particular negatives in question, if he were offered such a price for them as would repay him to make a diligent, possibly a prolonged, search for them, but so far as we can see he cannot be compelled by law to undertake it. Furthermore, he may not now have the negatives in his possession.

Let us now see if the Copyright Act can be applied in any way in such a case as this. If a copyright negative is sold, and the copyright in it is not properly assigned, the copyright lapses. In the present case there was no such assignment, nor could there be by the photographer, as the negatives being taken in the ordinary course of business, he had no copyright in them. That was vested in the one who paid for the portraits—presumably the writer of the letter—and it is still owned by him. It seems to us that if he now registers his copyright in the portraits he can take proceedings, under the Copyright Act, against anyone selling or exhibiting prints made from the negatives; but that, under the circumstances, gives him but little practical satisfaction, yet is, we think, all he can obtain.

The case serves to illustrate that portraits of persons taken in the ordinary course may, under some remote circumstances, be put to purposes of which the sitters certainly would not approve.

## A REFLEX ATTACHMENT.

Some time ago, finding the necessity for an "all-round" camera for holidays, etc., I devised a form of reflex camera. Of late numerous styles of such apparatus have been on the market, I think my model would claim a larger share of attention from those desiring a really "all-round" camera. For the benefit of such, I give here a somewhat detailed description of the model as first made—quarter-plate camera, which, however, after some usage, was found rather a small camera, and I would recommend 5 x 4 or half-plate in preference. The camera is of the Sanderson type—i.e., with swing-front and sliding to front motions—was the foundation. The shutter is of the focal-plane, with square opening. The reversing back of the camera was fitted to the focal-plane shutter so that it could be used either as required. The shutter was then built into the reversing back, with the mirror and horizontal focussing-screen. The front of this box was arranged to clip on to the back of the camera.

The points required some manipulation:—

- 1. The focussing-screen.
- 2. The mirror movement.

With regard to these, it was required to lessen the distance between the shutter and the focussing-screen as much as possible. A focal-plane shutter to the box would take up less room, and every little

weight of the focussing-screen was square, and gave only 4 in., not 5 in. This gave all the picture, and saved a little in length

The movement of mirror was so arranged that no springs

whatever were brought into requisition. Then no jolt or jar could arise to shake the camera at the time of exposure. The

A. Spring catch to hold camera in position. B. Focussing screen. C. Cut off blocks for light. D. Mirror. E. Shutter release, actuated by F. Arm of mirror.

weight of the mirror brought it down, so that the mirror was always in place for viewing and safeguarding the plate, except for the short period when the actual exposure was made.

It was not hinged at the top, for then the rise of the mirror would have described an arc, ever increasing the length of the box. Instead, the mirror was hung by its centre on two arms, the pivot being at end of arms close up to the blind of the shutter. The motion of the mirror was then an increasing arc for a very short part of its course, and then it rose vertically with a slight backward tendency. It was found that the action of the mirror took up less room than was required for the focussing-screen. In working it out this might be borne in mind, and probably placing the screen at an angle might be an advantage in more ways than one. The actual positions of mirror face, arm, and pivot were found by the aid of some pieces of cardboard and drawing-pins.

The body of the camera affixed to the front takes up more room, and 6in. to 6½in. focus lenses are required, but a 5½in. focus lens may be used if necessary by temporarily screwing the lens "inside."

Now let me give my reasons for designing such a model—in other words, the capabilities of the instrument. I often went

on holidays or cycle trips with either a hand-camera or a stand-camera, together with a casket of lenses. Often when I had one instrument I wished I had the other. To obviate this I designed this model.

The model as described was to be enclosed in a box, with double doors arranged to open so as to allow the stand-camera to be withdrawn, or for very long focus lenses. As a hand-camera, lenses of 5½in. or 6in. to 9in. or 10in. focus could be used. The release was arranged so that pressure raised the mirror, and as soon as the mirror reached the cut-off the release blind was released.

For stand-camera work, the two catches would be released and the camera drawn out of the box. Architectural and similar studies are rarely taken hurriedly, and the few seconds taken for detaching and replacing the stand-camera would be fully compensated for by the advantages gained in having a stand-camera with which to do work when required.

The diagram given will, it is hoped, make the positions of various parts readily understood.

HILTON GRUNT

## THE COLOUR-FILTER AND THE "ISOCROMATIC" PLATE IN ASTRONOMICAL PHOTOGRAPHY.

### III.

It has been suggested that, inasmuch as the objective in itself certainly possesses selective absorption, prismatic spectra were therefore very suitable, and in fact "quite the correct thing" for tests of relative sensitiveness. A series of spectra illustrating the absorption of the 40-in. objective (Fig. 10) shows, however, that beyond an absorption of about 200 Å. in the extreme ultra-violet there is

Fig. 10.

- a. Cramer instantaneous isochromatic unscreened.  
b. Varying exposures through 40-in. objective to same sky as in a, and showing absorption in ultra-violet.

no shift in the point of maximum sensitiveness, which remains constant at  $\lambda 4100$ . In previous papers the writer has demonstrated with some degree of completeness the incomparability of prismatic and diffraction spectra.

Inasmuch as we are mainly concerned at present with the action of the plate under a colour-filter, a series of exposures was also

made through a  $\lambda 5000$  filter (precisely similar to that made for Professor Lowell) to the spectrum of diffused daylight, and the measurements were measured and plotted. Similar exposures were also made upon the pinacyanol and pinachrome bathed "iso" plate, which also measured (for equal-exposure times). These exposures, together with their resultant measured curves, are now shown in Fig. 11.

Measurement of the relative areas of these curves gives a value which is practically equal.

Exact tests are desirable, however, to determine the remainder

Fig. 11.

constants of the plate, and to that end two isochromatic plates (bathed and normal) were exposed simultaneously in the revolving sector-disc machine behind the  $\lambda 5000$  filter to diffused daylight. Both plates were developed together at the one time, for the same length of time, and at constant temperature. They were then measured, and their curves are shown in Fig. 12.

Parallelism of the curves instantly indicates no change in sensitiveness by bathing, while the extraction of the relative speed gives a value of 1.1 times, or 10 per cent. in favour of the bathed plate. As this is a negligible amount in plate density, it therefore

by direct measures to selective light, the speed estimate obtained from the spectrum curves. Flat reproductions are also of the plates measured. It results, therefore, that there is direct gain in speed, but merely extension of spectral sensitiveness the effect of which will be presently shown.

Looking up the "tests" by Lowell, I quote from "Lowell Observatory Bulletin," No. 31, as follows: "Exposing a plate of this kind Mars, in our usual way . . . I took half the number behind the screen, and then, replacing it by the new one, took as many, both sets being exposed equally. . . . The results stood self-sessed, the detail came out sharper in the images taken with the yellow screen than with those taken with the yellow. . . ."

It would have been rather astonishing had the result not shown reference; for when we consider that we are dealing with two very different colour-filters, one of which transmits to  $\lambda 4800$  and of which are constructed for use with a plate possessing one high maximum in the yellow-green, it would hardly be expected that they should give as sharp results when used with a plate possessed of two active maxima. A more complete knowledge of the underlying principles would have predicated the result obtained. Had the  $\lambda 4800$  filter been intended to be used on such a

Fig. 12.

Exposure in powers of 2.

of plate, then it would have been made to absorb the red end

at an extended sensitiveness does not compensate for a single maximum, is very well shown in the accompanying illustration (Fig. 13), which represents a series of (a) three exposures with the telescope upon an instantaneous "iso" plate through a colour-filter at the critical focus; and (b) three more exposures upon the star, through the same filter, for similar lengths of time, at exactly the same focus, with estimated identity of seeing, but a red-sensitive plate. The increase in the size of the images, the loss in sharpness, is readily apparent, and needs no further comment.

Instead of a star we assume the case of the planet Mars, then we should have still a more decided example, because, according to Lowell, "the continuous spectrum of Mars is decidedly stronger in orange red than that of the moon, while at E the reverse is true," whence an increased action in the out-of-focus red. Making use of the colour-filter  $\lambda 4800$  with a red-sensitive plate, the results being made of more than double the amount of out-of-focus than would be effective if the filter were used with the plate which it was solely constructed for; by the lowering of sensi-

tiveness in the original isochromatic maximum, there is an increase in the burden of action which is thrown, first, upon the amount of blue light transmitted by the filter, and second, upon the region of enhanced sensitiveness at the red end, which is, equally with the blue, upon a rising branch of the objective's colour curve.

With the orange filter the blue is cut off entirely, confining the action to the yellow-green and red, i.e., to the flat portion and a single rising branch, therefore a step nearer monochromatic conditions. Were the action taken entirely out of the red and added to the yellow-green, it would be a step still nearer true monochromatism, but such a change would result simply in practically duplicating the original compensated curve of the instantaneous isochromatic plate (see Fig. 11). It therefore follows, and is beyond the possibility of doubt, that if this filter be used in conjunction with the instantaneous "iso," still sharper images will be obtained than with the red-sensitive plate, because the active rays will be more nearly monochromatic.

The value of exposure combined with steadiness of air as influencing sharpness, (1) by reason of monochromatism of light acting, and (2) by only making use of a minimum disturbance, is shown by the excellence of direct solar negatives made with the blue light on ordinary non-orthochromatic plates, at a point where the colour curve is rapidly approaching the vertical.

Fig. 13.

Star images with 40-in. telescope photographed under identical conditions of "seeing," focus, exposure time, and colour-filter ( $\lambda 4950$ ), but upon (a) isochromatic and (b) red-sensitive plate.

Important as is the correct appreciation of the isochromatic plate, colour-filter, and exposure, yet of an importance equally commensurate is the rôle played by an efficient backing. It is safe to state that in the delineation of astronomical detail the omission of backing causes at least a 50 per cent. loss of presentable results; while in each instance where such results have been attained they would have been 100 per cent. better had backing been used. It is equally safe to say that the lack of knowledge on this point is even greater than on the chromatic adjustment of plate and filter, and yet the principle involved is of obvious comprehension.

In practical work a backing composed of caramel mixed with a quantity of burnt sienna, or lampblack, has been found highly efficient. The compound is smeared heavily over the back of the plate with a stiff bristle brush.

When use is made of red-sensitive plates it would obviously be of no avail to colour the caramel red, because the modicum of light returned would be that to which the plate was sensitive, hence the best result for general work will be attained by the use of black. A damp wad of absorbent cotton readily removes the backing before development.<sup>10</sup>

To be most thoroughly effective, the backing should be in contact with the sensitive film and between it and the glass support. Such plates with a stained substratum are manufactured by several firms, but deficiency in the relative sensitiveness of the film has—so far—eliminated them from use in astronomical work.

<sup>10</sup> If the plate be laid aside for some time before development the backing should be removed, as its presence results in peculiar markings upon the film.

In concluding these remarks upon the influence of filters and isochromatic plates in astronomical photography, no claim is made for general originality; in the specific application to astronomy the treatment is new, but otherwise all points are matters of common knowledge to the photo-physical student.

We may summarise the foregoing in the following few sentences:

1. It is axiomatic that the closer the approach to monochromatic illumination, the more critically sharp will be the image. In practice the approach to monochromatic conditions is governed by the sensitiveness of the plate to the region under consideration.

2. With the use of the commercial isochromatic plate with its single secondary maximum in the yellow-green, there is no certain improvement in photographic definition (astronomically considered) by making use of a colour-filter of greater mean absorption than  $\lambda 4900 - \lambda 5000$ .

3. The two governing factors in successful astronomical photography of faint detail on illuminated areas (such as lunar or planetary work) are first, critical minimum exposure; and second, effective backing.

4. Given the necessary apparatus and material and assuming the ordinary ability to handle it, the personality of the operator exercises no influence upon the results obtained. These are, instead, relatively good or bad, as the "seeing" is excellent or poor.

ROBERT JAMES WALLACE.

### THE FRANCO-BRITISH EXHIBITION.

In order to see how far the rumours of incompleteness were correct, a representative of "The British Journal of Photography" paid a visit to Shepherd's Bush on Monday last, in order to discover what exhibits of particular photographic interest could be found in the many courts and galleries of the exhibition. Photographers who visit Shepherd's Bush with the intention of spending an enjoyable evening in the gardens and palaces, which already are well laid out and liberally provided with musical programmes, should enter the exhibition at the entrance close to the Shepherd's Bush Central London Tube Station, not the new station which now forms the terminus of the Central London Railway. A long elevated gallery connects this first-named station with the Court of Honour, and in this will be found the majority of the photographic exhibits which are at present discoverable. The official catalogue of the exhibition is apparently not yet available, but, so far as can be ascertained, the list which we give below includes the chief photographic exhibits.

A few yards on the left, after passing the turnstiles, will be found the collection of British pictorial photography, arranged by Messrs. Reginald Craigie, J. C. S. Mummery, and F. I. Spielmann. The collection is most tastefully displayed, and includes many pictures, which have been seen at past exhibitions of the Royal Photographic Society and the Linked Ring. A list of the pictures and their exhibitors will be found framed at the entrance to this sub-section.

A little further on, on the same side, will be found the frame of Messrs. Ilford, Ltd., a decorative scheme in oak and gold, containing thirteen prints or enlargements illustrative of the various manufactures of Ilford, Ltd., in the way of papers. These include prints on Ilford glossy P.O.P., "Bromona" bromide paper, toned, Ilford glossy gaslight paper, matt collodion, and "Platona" platinum paper. Noticeable among these prints is the portrait work of Mr. Elwin Neame, the high technical quality of which obtains a very good showing on the various brands of Ilford paper. A neat list of the exhibits, described in English and French, is provided in a hanging box below the exhibit.

Nearly opposite is a handsome display by the firm of Lafayette, which consists of an oak framework decorated in gold, with the photographs arranged on a background of pale green arras cloth. Messrs. Lafayette's well-known work in portraiture here obtains a very good representation, and includes some charming examples of miniature painting and one or two firelight portraits, which are particularly deserving of notice on account of their novelty.

A step or two further on, on the same side of the gallery, is an imposing collection of three-colour reproduction work by the firm of Carl Hentschel, Ltd.; a Hentschel colourtype reproduction of Mr. Charles A. Buchel's portrait of the King forms the centre of this

collection. In the centre of the gallery, close to the above is the stall of Messrs. Burroughs, Wellcome, and Co., hands made in mahogany, and displaying lantern slides showing various tones obtained by direct development with "tabloid" preparation; also negatives showing the result of tabloid intensification and reduction. Again, nearly facing Messrs. Burroughs, Wellcome, is the stall reserved to the Kinora Company, but at the time of our visit it was unoccupied by any exhibit.

A walk of a minute or two along the galleries brings us to the French section, devoted to printing and other pictorial arts, in which we found a section devoted to French photography. Evidently this section is not complete, but we were able to discover a panel of prints, presumably intended to represent the amateur pictorial work of France. It includes photographs by Paul Bouillay, G. Besson, Vicomte de Singly, A. de Cunha, and G. Roy. Guilleminot Boespflug and Co. exhibit in this section a number of bromide postcards, printed on rotary machines; but the greater portion of this section is evidently the work of the French professional photographers, and much of it appears to have been brought together under the auspices of the *Chambre Syndicale de photographes portraitistes*, a body having the same aims and objects as our Professional Photographers' Association. Among the exhibits which evidently have been selected to show all classes of professional portraiture, are the following:—Maurice Contere, Mathieu De Boyer, Otto, Nadar, Gerschel, J. Poyet, Aug. Peron, H. M. Panajon, Bordeaux, M. Sattagne, Chamberlin, Midgus, Otto (Durand) (Paris), P. Valle, Jules Boucher, Felix (Paris), Nadar, Dangereux, and Ed. Avrie. Among these will be found a number of portraits by M. Nadar of the French pioneers in photography, including Daguerre, Du Haumont, Lippmann, and others. There is also an exhibit of postcards and prints produced on the mangle manufactured in France under the trade mark S. I. P.

Arriving at the entrance court, which opens immediately at Wood Lane entrance to the exhibition, a doorway on the left side admits one to the British science exhibits, at the further end of which will be found a case of instruments by Messrs. J. H. Dallmeier & Co. Ltd., including examples of stigmatic lenses, and specimen photographic lens at various stages of its manufacture. Mr. Valentine, who have the sole rights for issuing postcard reproductions, have a number of kiosks in the grounds, and at these places make special show of their productions in this direction.

The stall of the Lumière Company should on no account be overlooked by the visitor, since it contains a collection of Autochrome transparencies made at Lyons, and which for brilliancy and technical quality are certainly in advance of anything which has yet been produced. MM. Lumière, who appear to have taken a personal interest in making of these results, are to be congratulated upon their selection of subject, and the photographer who has done any Autochrome work will applaud the magnificent technical success of the productions. The transparencies rely upon daylight for illumination, and therefore cannot be properly seen at hours when artificial illumination is necessary. The stall will be found on the right on entering the exhibition from Wood Lane.

### THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

The fifty-third annual exhibition of the Royal Photographic Society will be held at the New Gallery, 121, Regent Street, London, W., from September 17 to October 24, inclusive, and will be divided into the following sections:—I. Pictorial photographs. II. Scientific and technical photography, and its application to processes of reproduction, also apparatus for scientific photography. III. Screen and colour transparencies. IV. Professional and commercial photography. V. Photographic apparatus and material. No collection of wall space are made in sections I, II., and III., exhibitors must fill up an entry form and enclose it with the exhibits. Exhibits sent by carrier must be addressed to the Society's agents, Messrs. Bradley and Co., 81, Charlotte Street, Fitzroy Square, London, and must be delivered, carriage paid, on or before Tuesday, September 1. Exhibits delivered by hand must be presented at the address, unpacked, between 10 a.m. and 6 p.m., on Wednesday, September 2. Any exhibits presented after either of the

will be refused, also any upon which carriage has not been taken in full, and the Society does not undertake to acknowledge receipts of exhibits.

All photographs, except lantern slides and transparencies, must be framed, except in the case of foreign and colonial exhibitors. These must, however, be mounted, and for all accepted the Society provide frames free of charge. In section I. each photograph must be framed separately, and have a label affixed to the back giving the name and address of the exhibitor, the title or description of the photograph, and a number corresponding with that on the entry form; the only inscription allowable on the front of the photograph, picture or mount being the title of the picture and the name of the exhibitor.

The selecting and hanging committee of the pictorial photographs (section I.) is composed of the following well-known workers:—Messrs. W. R. Bland, E. T. Holding, Charles F. Inston, Furley, J. C. S. Mummery, G. A. Storey, A.R.A., and B. Gay Kingston. Entries in this section may be by any process, but no exhibitor may submit more than six.

In sections II. and IIA. the work of selecting and hanging will be directed by the following experts:—Messrs. Conrad Beck, C. P. Ler, A.R.C.Sc., Douglas English, M.A., C. E. Kenneth Mees, F.C.S., A. J. Newton, J. Sinclair, E. J. Wall, and Major-General Waterhouse, I.A. Section II. includes exhibits in scientific photography, together with apparatus used in photographic investigation; also those relating to any photo-mechanical process of reproduction.

Transparencies for exhibition in section IIA. must be varnished, protected by a cover glass and bound round the edges. They must be framed, but the title, author's name and the number corresponding to that on the entry form must be written legibly on the back or binding. These will not be shown in the lantern except by arrangement with the author. Medals will no longer be awarded in section II.

In previous years, a charge will be made for space in section for professional and commercial photography, and application for should be made by letter, not later than July 11, to the Secretary, Royal Photographic Society, 66, Russell Square, London, W.C. The title or description of the exhibits must also be in the Secretary's possession not later than September 8, if it is desired that particulars shall appear in the catalogue. Orders for photographs may be given at the exhibition, but no delivery there will be allowed.

The Central Hall will be reserved for exhibits of photographic apparatus and material (section IV.), and floor space will be let for erection of stalls, all designs for which must be submitted to the Organising Committee for their approval. Entry forms, which when ready, may be obtained, together with full particulars, from the Secretary, Royal Photographic Society, 66, Russell Square, London, W.C.

## Patent News.

*Process patents—applications and specifications—are treated in the Mechanical Notes.*

The following applications for patents were received between May 18 and 23:—

**STEREOSCOPIC APPARATUS.**—No. 10,750. Improvements in and relating to photographic, stereoscopic, and like apparatus. Luiz Augusto Teixeira de Aragao, 11, Southampton Buildings, London.

**FRAMES, ETC.**—No. 10,802. Improvements in photographic processes and in frames for use therein. James Mark Child, 37, Chancery Lane, London.

**FLASH LAMPS.**—No. 10,844. Improvements in flash lamps for photographic purposes. John Theodore Groves, 36, Fitz-James Avenue, West Kensington, London.

**SENSITIZED PHOTOGRAPHS.**—No. 10,887. Improvements in and relating to the colouring of sensitized photographic surfaces. Bernard James Cooper and Ronald Kesterton Inman, 60, Queen Victoria Street, London.

**SENSITIZED SHEETS, ETC.**—No. 10,970. Imparting flexibility to sheets, strips, or strips charged with or carrying chemicals. Self-Develop-

ing Plate Co. and Butler Humphreys, 7, Southampton Buildings, London.

**APPARATUS.**—No. 11,010. Improvements in or relating to apparatus for use in photography. William Edwin Hickling and Thomas Matthews, 111, Hatton Garden, London.

**ROLL-FILMS.**—No. 11,162. Improvements in the mode of and means for developing photographic roll-films. James Wyndham Meek and David Brown Thomas, 77, Chancery Lane, London.

**MOUNTS.**—No. 11,225. Improvements in picture, photographic, and other mounts. Thomas Smith Jacob, Hereford House, Southend Green, Hampstead, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**TONING PROCESS.**—No. 10,258, 1907. The invention consists in a process of converting images of silver, such as lantern slides or bromide prints, into coloured compounds capable of being dyed, colouring these compounds, and removing the base (or compound) on which the colouring matter was deposited. Silver iodide has been found the best compound for the purpose. The print or transparency is treated as follows:—The silver print, obtained in the ordinary way on transparency emulsions of a suitable kind, is transformed into a print consisting of silver iodide or silver bromide, silver chloride, silver ferrocyanide ( $\text{Ag}_2\text{FeCy}_6$ ), double compounds of silver and copper, or of silver and mercury, or other compounds capable of being coloured directly, whereupon the colouring is effected in suitable colouring baths. After a short time the deposit of the colour on the silver compound will have taken place, whereupon the excess of colour is removed from the gelatine film by a short soaking. The silver iodide prints thus obtained, which in respect of transparency even of the deepest shadows are especially suited for projection purposes, must be subjected to a fixing process for eliminating the silver compound from the picture when used for polychrome photography, which requires completely transparent pictures. If appropriate colouring material has been selected for the colouring, after treatment with thiosulphate of sodium, an insoluble colour picture remains.

Quinoline red may be given as an example of a suitable colouring material which may be used for colouring in a dilution of 1:2000 or weaker, fixing then taking place in an acid fixing bath. Before the colouring takes place the silver is transformed into compounds, which can be removed by the usual fixing medium. In order that no injury to the colour picture may occur owing to the employment of such a medium, only basic colouring materials should be used. Colouring materials of any kind may, however, be used if the precipitation of the colouring material in the form of an insoluble lake or salt is effected by the addition of appropriate substances to the fixing solution. This addition depends upon the nature of the colouring material. When the colouring is effected by means of a basic colouring material, tannin is added to the fixing bath; when colouring with acid colourants, metallic salt solutions are added. Other colourants form insoluble or difficultly soluble iodides, so that an addition of iodide of potassium to the fixing solution leaves behind a colour picture. In any case it is merely a question of adding to the fixing bath (solvent for silver iodide or other silver compounds) those substances which, with the colouring material, give insoluble coloured compounds. Dr. Arthur Traube, 16, Wieland Strasse, Charlottenburg, Germany.

**CAMERA FRONTS.**—No. 2,525, 1908. The object of the invention is to prevent the pushing in of the lens-front of a folding camera before the lens is in the correct position. This can be done both by displacing the lens-carrier and by displacing the lens-panel. Stop pieces are provided in front of a pin which is fixed to the base-board to prevent the pushing back of the lens-carrier. When the lens is returned to its central position the pin can pass through slits which are provided in the stop pieces so that the camera may be closed. Fabrik Photographischer Apparate auf Aktien vormals R. Hüttig und Sohn, 76, Schandauerstrasse, Dresden, Germany.

**STEREOSCOPIC PROJECTION.**—No. 17,955, 1907. The invention relates to a device for looking at stereoscopic projected images, especially

living pictures, in which device the openings for the eyes are alternately covered by a rotating screen or wing, which rotates synchronously with the screen or wing that covers alternately the object-glasses of the two projectors. These latter project on the same spot the images intended for the right eye and those intended for the left eye.

A device, consisting of (1) a frame provided with a handle and with eye openings, and (2) a screen or wing rotating in front of these openings, synchronously with the screen or wing of the projector, by means of an electro-motor placed in the apparatus. The double-leafed screen or wing is directly fixed to the shaft of the motor, the screen or wing being of a semi-transparent red-coloured material, and decreasing in thickness from the centre towards the periphery. The motor consists of a double-T armature rotating in a field winding, so as to avoid iron poles. The armature winding and the field winding are fed through a cable containing several wires placed in the handle of the apparatus, so as to avoid the use of brushes. Marius Nicolai Topp, 3, Horsetory, Odense, Denmark.

**FILM PACKS.**—No. 18,860, 1907. The invention relates to the envelope method of carrying plates for exposure, and particularly to the dark-slide, which is provided externally with a fixed mouth-piece receiving the extremity of the envelope containing the sensitised plate and internally with a movable spring plate ensuring the exact focussing of the sensitised plate and at the same time, by means of a sliding piece acting thereon, the closing of a sliding piece inside the dark slide, so that, when the sensitised plate is in position, it will be possible to take away the envelope from the mouth-piece of the dark-slide without any risk of access of light. The envelope remains fully closed until the moment of introducing the plate into the dark-slide, and is again closed when the exposed plate is removed from the dark-slide. Silvio Mela, 11, Via S. Luca, Genoa, Italy.

**ROLLER-BLIND SHUTTERS.**—No. 25,537, 1907. In this type of roller-blind, for which protection is claimed, the slats are connected by chains, the links or sections of which consist of plates having their ends bent to form hooks. These latter engage with one another so that when the shutter is rolled or unrolled there is relative movement over the whole of the contact surface between adjacent links. Arthur Wells, 65, Alexandra Road, Southend, Essex.

**PROCESS PRINTING FRAMES.**—No. 24,617, 1907. The invention consists of a printing frame of the kind in which equal distribution of pressure is obtained by exhausting air from between the transparent front plate of the frame and the movable back plate. The new arrangement consists of an automatic valve controlling an aperture in the back plate and adapted to co-operate with a pump directly placed on the back plate over the valve. James Pritchard and Harold Pritchard, 167, Rosebery Avenue, E.C.

**STEREOSCOPES.**—No. 5,742, 1908. The invention consists of a collapsible hand-stereoscope, with electric illumination, the source of current for electric miniature illumination being contained in a suitable part of the stereoscope apparatus. The handle is detachably fixed to the base plate by a bayonet joint, and the slide bar is attached to the base plate by a hinge joint. Albert Edward Foote, 5A, Gegensburgerstrasse, Berlin, Germany.

**PHOTOGRAPHIC ARC LAMPS.**—No. 3,700, 1908. The present invention is an improvement on the lamp described in Patent Specification No. 9,574, 1907 ("B.J.," September 13, 1907, page 697), in which pairs of carbons of several arc lamps are placed in front of a reflector and arranged to produce a favourable distribution of the light. In this apparatus the individual carbons are secured to parallel rods or holders swinging about stationary pivots, the carbons belonging to one arc lamp being arranged at opposite ends of adjacent rods, and with their ends directed towards each other. The holders are connected to one another in such a way that, upon rocking one of them, the other holders are rocked through the same angle, whereby all the carbons are simultaneously moved the same distance towards or away from each other. If in this apparatus pairs of carbons of unequal sizes are used, some of the arc lamps will sometimes not be lighted, because the longer carbons are in contact with each other, while the shorter ones have not yet come in contact with each other. A further automatic regulation is impossible on account of the rigid con-

nection of all the carbon holders. Thus, the shorter carbon not be lighted unless they are adjusted by hand. The object of the improvements is to provide an apparatus of this class in which all the arc lamps will safely and automatically be put in operation. For this purpose, the pairs of carbons are not connected with one another, but the carbon holders are connected independently of one another to their common adjusting mechanism. Jean Schmidt, 70, Bleichstrasse, Frankfurt-am-Main, Germany.

The following complete specifications, etc., open to public inspection before acceptance under the Patents Act, 1901:—

**PRINTING PLATES.**—No. 9,500. Process for the production of printing plates. Roux.

**STEREOSCOPY.**—No. 10,493. Method of stereoscopy and apparatus for the application of this method. Balmigère.

## New Trade Names.

**LION'S HEAD BRAND.**—No. 302,062. Cinematograph films bearing taken photographs. George Howard Cricks and James H. Martin, trading as Cricks and Martin, Ravensbury Lodge, Leam Road, Mitcham, Surrey, cinematograph film makers. April 10, 1908.

**LINGRAIN.**—No. 302,161. Photographic papers. John J. Lingrain and Sons, Ltd., Kemble Street, Kingsway, London, W.C., photographic paper and apparatus manufacturers. April 10, 1908.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Bichromated Plates for Copying.

Maybe the reader has tried at some time (says Mr. W. S. I. writing in the "Photographic Times" for May, on the recovery of fogged plates with a bath of potash bichromate and hydrochloric acid) to copy a picture, such as an engraving or pen-and-ink drawing, where it was desirable to obtain a negative containing clear lines on an opaque ground, but having used an ordinary rapid plate, the negative turned out flat, with veiled lines on a translucent ground. This is where a bichromated plate will prove a satisfactory substitute for the special slow contrast plates made especially for copying, and which few amateurs keep on hand. For this purpose any rapid plate can be dipped when wanted, and the amount of contrast it is desired to obtain regulated by changing the strength of the bath, but for copying a 1 per cent. solution of bichromate will probably be found about right. If desired, the plates can be exposed as soon as they are surface dry, doing away with the trouble of drying in the dark.

### Printing on Collodion Paper.

Mr. W. Foster Brigham, writing in "Photographic Scraps" for May, on the new Ilford collodion paper, says: Any of the average negatives will give good prints, but they should preferably be rather more contrasty for black tones obtained in two baths. If warm tones, ranging from red-brown, chocolate-brown, to black, are wanted, printing should be only slightly darker than required when finished, but for double-bath tones printing must be taken much further. The shadows may bronze, but no more should be taken of this. Print until the high lights are well defined. When ready, the untrimmed prints, in any number up to two hundred, are washed rather longer than it takes for milkiness to disappear, time varying, of course, with the number of prints. Since all collodion prints are liable to curl it will be a great saving of time and irritation if this tendency is checked at the outset. To do this put about half an inch of water in the dish, place the prints in it, one by one, face down, pressing each as flat as possible on the bottom of the dish. If necessary, a little water occasionally. When all have been so treated pour the water off and squeeze the prints to remove as much moisture as possible, after which leave for five minutes. At the end of this

minutes' hand washing in constantly changed water should be the soluble silver and the preserving salts.

### Safe Transmission of Photographic Prints.

A strange (writes the editor of the "Photo-Era," in his June number) that workers sending us prints persist in enclosing them in sheets of cardboard with the corrugations running in *one* direction. Photographs sent thus, or placed against one single sheet, seldom reach their destination safely. Prints should first be placed in soft paper, and then placed between pieces of corrugated cardboard the kind which is covered on both sides—with the corrugations running in *opposite* directions.

## New Books.

PHOTOGRAPHY WITH FILMS.—No. 82 of the "Photo-Miniature" (Arn and Ward, Ltd., 6d.) deals with this subject, and serves a purpose in dealing with the various modern appliances for development of roll film and the exposure and after-treatment of films. The "Notes and Comments," which have been a commendable feature of the "Miniature" since its foundation, are brightened by paragraphs which are unmistakably Bedding-Whistler as frontispiece we have the reproduction of an English tape by Thomas Bedding, F.R.P.S. Can it be that our friend abandoned his intention of writing the epitaph of the Salon and of appealing to the Selection Committee?

## New Apparatus, &c.

"Vesta" Pocket Camera. Made by Adams and Co., 24, Charing Cross Road, London, W.C.

A camera with a full range of movements reduced to the smallest dimensions is the very strong claim which Messrs. Adams make for their new instrument, the "Vesta." And the use which we have been making of the camera within the past few days fully justifies in our opinion the makers' contention as to the practical facilities provided within the extraordinarily small space of  $4\frac{3}{8} \times 3\frac{3}{8} \times 1\frac{1}{4}$ . The movements are our own, and apply to the smaller of the two sizes of "Vesta" which are at present made—namely, the  $3\frac{1}{4} \times 2\frac{1}{4}$ . We confess that on other grounds than that of bulk we would

the  $3\frac{1}{4} \times 2\frac{1}{4}$  size in preference to the quarter-plate. The conditions are all in its favour, focussing is practically necessary, and a  $15 \times 12$  enlargement from the smaller plate is as sharp as, if not sharper than, that from a quarter-plate at the same angle. The "Vesta" is of the falling case-board type. The lens front is extended on lazy tongs and affixed to the body by attaching two catches to a pair of studs. The front

is kept pressed against the studs by two springs, one of which is shown in the drawing of the open camera. When set up the front is extremely rigid, and is fixed in the exact parallelism with the plate necessary with the modern flat field anastigmat of large aperture. The operation of opening the camera and preparing it for an exposure is the work of a few seconds.

Perhaps the most notable feature of the "Vesta" is the rise of front available both ways of the plate. The camera is built the vertical or "portrait" way of the plate, and the lens panel has a rise of over three quarters of an inch in this direction. But the whole lens front also moves in the other direction, and provides a rise of  $\frac{5}{8}$  of an inch "the landscape way" of the plate. Movements of these dimensions on a plate  $3\frac{1}{4}$  by  $2\frac{1}{4}$  are, as the reader knows, amply sufficient for all but the most extraordinary requirements. In the case of both movements the lens on being pushed down is automatically stopped opposite the centre of the plate.

Of the other movements, the focussing scale is graduated from infinity to two yards, but, as we have said, in the case of a lens of four inches focus, such as that fitted to the "Vesta," the depth of focus or field is very great, and the necessity of the exact use of a focussing scale is far less imperative than when using lenses of longer focus. The finder is of the direct vision type and is affixed to the lens front, with which it moves when raised in either direction, thus giving, in conjunction with the sighting rod on the back of the camera, a better approximation of the displacement of the picture due to the rise of front than when the finder is a fixture. The "Vesta," too, is fitted with two bushes for affixing it, either way of the plate, to a tripod.

The shutter fitted to the camera is the well-known "compound" with time and bulb adjustments and a range of speeds instantly alterable before exposure merely by turning the adjusting disc, say, from the starting point (1 second) to its extreme limit (1/250th of a second).

A focussing screen is provided with the camera and is held in the back by a convenient lever clip, which likewise retains firmly but instantly releases the single metal dark-slides, six of which are included in the outfit. Messrs. Adams make the body of the slide of aluminium, the slide only of steel, thus saving a good deal of weight, while avoiding the danger of fog which is involved in the use of an aluminium shutter. The shutter of the slide, after it has been withdrawn, can be fixed behind three clip heads on the back of the camera, and thus secured from risk of becoming bent or damaged.

The whole apparatus is made largely in aluminium alloy, and is covered throughout in black leather. When closed for carrying the whole of the working parts are encased, and the finder, it should be mentioned, automatically turns over and folds itself within the camera as the base-board is shut down. Altogether the "Vesta" is a triumph of construction and a camera which will serve the tourist well amidst the greatest variety of subjects. Complete, with Ross Homocentric  $f/6.3$  and six single metal slides, its price is £10 10s., or with Zeiss Protar  $f/6.3$  £13 15s. In quarter-plate size these prices are £12 and £16.

The "Giorno" Folding Reflex Camera. Made by M. Husson, 207, Avenue de la Reine, Brussels.

The advantages of the reflector type of camera have been so widely appreciated during the past few years, partly, no doubt, in

consequence of the notice drawn to this description of instrument by the exhibition at "The British Journal of Photography," that no arguments need to be assigned in its favour when proceeding to describe still another addition to the many reflex cameras. There is, however, one thing against all reflex cameras, and that is their size. Not an immense objection perhaps in the minds of many, but nevertheless an obstacle to the adoption of a camera of this kind on many excursions when luggage is being cut down to the minimum. One or two recent models of reflex taking a smaller plate have to some extent obviated the difficulty, but a new solution of the problem is provided by a new reflex camera, which so far as we know is the first of its kind to embody the reflex principle in a folding or collapsible camera. We have recently had the opportunity of closely inspecting the camera possessing this good feature. Its inventor and maker lives in Brussels, and it is therefore to be supposed that members of the Photographic Convention, on the occasion of their meeting there in July, will be afforded the opportunity of inspecting an instrument which may certainly be described as a notable advance in photographic apparatus.

Giorno Reflex Camera.

The "Giorno," as the camera is called, is shown in the drawings, from which it will be seen that the portable character of the apparatus is not obtained at the sacrifice of extension: the 9 x 12 cm. camera (a little larger than quarter-plate) allows of lenses up to 8 inches focal length being employed. It closes to a space of about 3 x 6 x 6½ in., being then just about the size and shape of the folding hand-stand cameras of the fall-down base-board pattern, which has become universal since its introduction in America. In opening the camera there are but two movements. The one draws out the lens front, which snaps into position on its two hinged side struts; the other releases the focussing hood, which is practically self-erecting. The camera is closed in the same expeditious way, and as the moving parts do not interfere with the part of the apparatus carrying the sensitised plate the latter can remain ready for exposure. The work of a few seconds, therefore, makes the camera in readiness for an exposure. It should be stated that the bellows extension seen in Figs. 1 and 2 should be racked in before closing the camera.

So far, we have spoken chiefly of the portability of the camera, but its features as a reflex camera entitle it to commendation. The "Giorno" is fitted with a focal-plane shutter with a slit adjustable

up to the full length of the plate. The longer exposures of and 1-5th of a second can be given, often a useful means of full exposure. The higher speeds up to 1-1000th and less are obtained by increasing the spring tension and reducing the width of the slit. A very convenient feature of the shutter is the change from "instantaneous" to "time." The front has a sliding movement, though our own experience is that it should have been provided. The shutter release can be actuated from the side, and the camera is built to receive dark slides, changing slides, or other convenient plate or film holder. Its design and workmanship has impressed us as most practical, and though the instrument which we saw could be improved upon in details its features are certainly those which will commend it to serious camera users. The price of the camera in 9 x 12 cm. size (quarter-plate), without lens, is 270 francs (say £11), inclusive of six single metal plate-holders.

The "Finsbury" Head Rest and Screen. Sold by O. Sichel & Co., 52, Bunhill Row, London, E.C.

At Messrs. Sichel's well-arranged place of business, which, as people may not know, lies within six minutes' walk of Moorgate Street Station and within a stone's-throw of the Old London tramcar route from Bloomsbury and Holborn, we have recently inspected two very useful and novel studio accessories just placed

the market as the "Finsbury" Head Rest and the "Finsbury" Screen.

The former, shown in the first drawing, is a commendable version of the old-fashioned clamp for the human head, in that it provides simply a small surface, against which the sitter can be placed.

does not, by its appearance and application, convey the unpleasant sensation that the operator is planning a new method of garrotting or some other form of sudden death. The "rest" is inoffensive to

at the chief point in its favour is the flexible adjustment by which it is placed anywhere without turning a single screw or using any kind of support. The rest is attached to a support composed of spirally constructed tube, something after the manner of the gas tubing now in common use. In practice the device is convenient. A touch, and the "rest" is placed where it is desired without, as we have said, any fixing whatever. The apparatus is sold at 35s.

The head screen is on the same principle. Like the head rest, the position of either of the two screens can be separately altered by the same spiral tube construction. The height of the screens from the ground is also separately adjustable by a quick-movement. Both pieces of apparatus have a smartness of appearance which certainly represent the acme of convenience in use. The price of the head screen is 50s.

"Blitz" Double Anastigmat, Series III.,  $f/6.8$ . Sold by the City Sale and Exchange, 90 to 94, Fleet Street, E.C.

This is a symmetrical doublet with triple cemented single components. The lens submitted to us is of  $9\frac{1}{2}$  in. focal length and aperture of about  $f/7.2$ , according to our measurements, and it is tested to cover a whole plate, which it does with very good definition. It gives very good results as a copying lens, and only shows a very slight curvature of field with distant objects. It appears extremely well corrected for astigmatism, and it is a remarkable cheap instrument, seeing that a  $4\frac{1}{2}$  in. lens only costs £2 10s. City Sale and Exchange offers to send a lens on seven days' free trial, and will undertake to refund the money if not found entirely satisfactory and up to specification in every way, provided it is returned in perfect order.

Eastman Plate-Developing Tank. Made by Kodak, Ltd., Clerkenwell Road, London, E.C.

The Kodak Co., having done all that seems humanly possible to simplify and standardise the development of film exposures, now places on the market a tank for the development of plates, which for convenience in use is altogether admirable.

Vertical development—in a tank—is, as we have frequently pointed out, a manipulative method of particular advantage to the professional, who often has not the space at his disposal sufficient to allow of his dealing quickly with the results of a day's work in the studio. In summer the evening is usually the time preferred for development on account of the comfort in working, and hence the provision of devices which save time and labour, not to say developer, has been looked into of late

any alert professionals. We are writing now not in special advocacy of a "time" system of development, although studio negatives are of all others the most adapted to the system—inasmuch as they are almost invariably correctly exposed—but we are insisting on the convenience and economy of the tank method as compared with the dish method. Our own practice, whenever we have any number of exposures to deal with, is always that of the tank. It may or may not decide the point at which the negative is removed

by rule—most usually we decide it by inspection, but that, from the practical standpoint, is a matter of no greater importance than the mechanical convenience of the vertical system.

The "Eastman" tank possesses several important qualifications for the duty of thus holding the plates for development. It has strength and lightness. Its substance of nickelled metal fits it to withstand long usage. It provides for the rapid insertion of the plates into their grooves; if necessary, in total darkness—a facility which, so far as we know, is not provided in any similar tank. This is done by the use of a loading block shown in the figure. This block consists of a stout framework in which the plate rack is temporarily fastened (for loading) by means of a clip. Across the aperture of the framework moves a board in which is a slit wide enough to take the pair of plates which go into each of the

six grooves of the tank. The slit registers with the groove of the tank, and the pair of plates have only to be slipped into it to pass into the rack. The slit is narrowed at the ends so that the surfaces of the plates are not rubbed in their passage. The slit is then moved on to a position over the next groove of the rack. This is done by pressure on one of two metal studs, and in this way all six grooves are quickly charged with plates. We can testify to the advantage of this plan in practice. No getting the plates across their proper grooves. In ordinary work it is a comfort, and for panchromatic plates practically indispensable.

The plate-rack is well perforated and provides for proper circulation of the developer. The tank is fitted with a light-tight lid, which is held securely down by a special type of clamp, and lastly, a dial and movable pointer are affixed for use in removing the plates from the developer at the expiration of a given time.

The instruction booklet of the Kodak Company gives formulæ, times and temperatures for the use of the "time" system. The

data will certainly be useful to the photographer in deciding on his own practice, which is bound to vary with the plate employed and the type of negative required. Yet be the method "time" or "inspection," the worker has in the Eastman tank a thoroughly well made and workmanlike piece of apparatus.

The tank is made in two sizes for 5 x 4 and 7 x 5 plates respectively. The former (12s. 6d.) is provided with an adapter for quarter-plates. The latter (16s. 6d.) is similarly provided with adapter for half and  $6\frac{1}{2}$  x 4 plates.

AIRCRAFT OUTFITS.—By the courtesy of Messrs. Dorendorff and Co., Christmas card publishers, of Worship Street, London, E.C., we were recently afforded an opportunity of inspecting an air-brush

department just installed for them by the Airolstyle Syndicate, to whose technical and business manager, Mr. Aufholz, the details of the equipment are due. The installation provides accommodation for four operators, each of whom is provided with a two-brush supply of compressed air, while each is also given a separate hood from which all superfluous spray is quickly drawn and discharged into the outer air. The brushes themselves, which are of the Airolstyle new pattern, and the mechanical accessories which are so essential to economical use of the air-brush on a large scale, have evidently been the subject of very careful study by the technical management of the Airolstyle Syndicate.

THE "MULTISECTO."—Messrs. J. Fallowfield write:—Readers of "The British Journal of Photography" will doubtless be interested to learn that two new ideas have been successfully worked with the "Multisecto" apparatus which you kindly reviewed some few weeks ago. Two of my customers have written to me stating that they find the "Multisecto" excellent for Autochrome photography. The long panel shapes make excellent pictures on half-plates, and, of course, save considerable expense in cost of plates. Again, a professional photographer who bought a "Multisecto" to use with a half-plate Sanderson discovered that by using No. 10 Secto, six views could be taken and printed on postcards, and he has obtained a large number of orders from the stationers and photographers in the town by making a series of postcards each containing six different views, and he is obtaining double the price for these postcards with practically the same amount of work.

## New Materials, &c.

"Challenge" and "Artro" Self-toning Papers and Postcards. Made by The Challenge Works, Macclesfield, Cheshire.

Samples of these materials, to which we have had an opportunity of giving a trial, have given us very excellent results. The "Challenge" papers are made in glossy and matt varieties, and of several tints, such as grey, pale green, buff, and salmon. In all cases we found the papers to give brilliant tints and to assume a very agreeable brown tone in a hypo bath of three ounces per pint. This bath is used for six minutes. If one double the strength be used the tone is purplish, and though our own preference is for the brown tone, there are no doubt many who will wish to take advantage of the range given by the paper.

The "Artro" is a cream-crayon self-toning paper, of very pleasing "carbon" surface. Its manipulation is exactly the same as the papers just described, but its peculiar surface and harmonious effects specially fit it for portrait work and certain landscape results. All the papers are put up in packets (6d. and 1s.), in gross boxes and in sheets. The postcards are also sold in dozen, hundred, gross, and thousand packets. We can certainly recommend application to the Challenge Company for samples and prices of these materials.

In connection with their papers, the Challenge Works, it should be added, are offering prizes to £10 for the best prints on their self-toning and gaslight papers. There is a bonus to the dealer from whom the successful paper is obtained.

Materials for Oil Printing. Sold by Messrs. Charles Roberson and Co., of 99, Long Acre, London, W.C. (and 155-6, Piccadilly).

Messrs. Roberson send us some samples of their pigments and brushes for oil printing, which on trial prove to be eminently satisfactory. The brushes are fitch hair dabbers of the so-called "deer's-foot" form. They are slightly rounded at the end, which is a distinct advantage, and though we used a quite new brush that had not been previously softened by soaking, no broken hairs were to be seen on the print. The pigments are in china pots, which hold a liberal supply, and the black pigment works excellently. It is very finely ground, and readily gives the smoothest possible tint. Used undiluted it is just the right consistency for contrasted effects, but it can be softened to any extent with a special medium, also supplied by Messrs. Roberson. As the smallest possible amount of this medium produces a very marked effect it must be used with caution. Eight different pigments are supplied—black, sepia, burnt umber, warm sepia, indigo, burnt sienna, raw umber, and Payne's grey—and the price is 1s. per pot. Messrs. Roberson offer

to supply any colour to order, so at last a complete palette is commanded by the oil printer. The brushes are in twelve Nos. 1 to 10, and Nos. 12 and 14, the prices varying from 6s. 6d. The medium is 6d. per tube. Messrs. Roberson are supplying hog-hair brushes for large pigment work at prices 4s. to 9s. They are metal-mounted, and hold their hairs very secure. A special varnish for oil prints is also available at 1s. 6d. per pint. It is stated that this should not be used until about three days after pigmenting the print. We have not tried varnishing oil prints, but probably in some cases it may have a very desirable effect.

We note that Messrs. Roberson also supply pigments finely ground in spirit for use in gum-bichromate work, and that they are generalising in colours and materials required by pictorial photographers. Their list contains many useful items, and photographers should make a point of seeing it.

REDUCTION IN THE PRICE OF PLATINOTYPE PAPERS.—The Platinotype Company, 22, Bloomsbury Street, New Oxford Street, announce a reduction in the prices of platinotype papers. It will be remembered that an increase in prices was made a little over a year ago as the result of a continued rise in the price of platinum. The present reduction restores the price to its original level, or, in some cases, to a little over. Under the new tariff a three sheets of "Black" paper, 26 x 20, costs 8s.; Sepia or J. 9s. The full price list and book of instructions is obtainable from the company.

## CATALOGUES AND TRADE NOTICES.

MESSRS. BISHOPS, of 466, Holloway Road, London, N., have issued a new edition of their photographic catalogue, which is full of particulars of practically everything needed by the photographer both in apparatus and accessories. The list is well illustrated, and photographers in the north of London would do well to see a copy, on page 2 of which particulars as to free delivery of goods to London and suburbs will be found, together with special terms of delivery for country customers.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK

FRIDAY, JUNE 5.

Liverpool Amateur Photographic Association. Excursion to Oxford.

SATURDAY, JUNE 6.

South Suburban Photographic Society. Excursion to Epping Forest.

Winney.

Aberdeen Photo Art Club. Outing to Banchoy.

Leeds Camera Club. Excursion to Knaresborough.

United Stereoscopic Society. Excursion to Winchester.

South London Photographic Society. Excursion to Midhurst. Dr. Ever.

MONDAY, JUNE 8.

North Middlesex Photographic Society. Outing to Ely. H. W. Fincham.

TUESDAY, JUNE 9.

Royal Photographic Society. No Meeting.

Hackney Photographic Society. Questions and Answers.

Rugby Photographic Society. Midland Photographic Federation Conference.

Outing to Oxford.

Handsworth Photographic Society. Midland Photographic Federation Conference.

WEDNESDAY, JUNE 10.

South Suburban Photographic Society. Special General Meeting. Portrait Print Competition.

THURSDAY, JUNE 11.

Handsworth Photographic Society. "Printing by the Donisthorpe Process."

A. E. Cope.

London and Provincial Photographic Association. "Photographic Chemistry."

W. H. Dawson.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held June 2, the president, Mr. J. C. S. Mummery, in the chair.

A paper was to have been read by Dr. S. E. Sheppard on the theory of colour sensitising, but owing to the author having been delayed in travelling from Paris to London he was unable to be present. In his absence Dr. C. E. K. Mees gave an informal paper on one-exposure three-colour cameras, in special reference to the design by Mr. Edwin T. Butler, the construction and printing of

Dr. Mees explained by means of an actual instrument. He pointed out that the difficulties in designing a camera of this kind were very considerable. They consisted chiefly in obtaining a place of constant colour sensitiveness. It did not matter much if the actual colour of the plate varied, but if its colour sensitiveness to different parts of the spectrum varied, even within small limits, it was difficult to make a camera to make adjustments for it. Also, considerable care in the optical construction was necessary to secure images of identical size and to avoid also the formation of double images from the two transparent reflectors. As regards the plate, Dr. Mees found it best to use the same plate for all three negatives. He preferred a pinacyanol-bathed plate, since this sensitiser did not alter the general sensitiveness of the plate, and as it was a fairly uniform dye the ratio of colour sensitiveness varied but slightly. As to the arrangement of the filters he had found it most advisable to use the green sensation negative by the direct rays; the red sensation negative was taken at the focus of the image reflected from the first reflector, whilst the blue in that reflected from the second reflector. He adopted the principle of Mr. Butler in making the third negative for the colour complementary to the filter above it, that was to say the first reflector forming the image of the red sensation negative was greenish blue, that for the blue sensation negative was yellow. He explained at some length the methods employed for testing the parallelism of the glass filters and reflectors, and explained that, as constructed in the camera exhibited, the sizes of the image were equal to within 1-100 of a mm. The filters were of "optical plate," and by visual examination. The lecture promoted a brief discussion, in which Messrs. E. J. Wall, C. P. Butler, H. H. O'Farrell, and others took part.

**DOON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At the meeting on Thursday, May 28, Mr. W. R. Stretton in the chair, Mr. Verbury demonstrated "Sinop," a process that might be called the amateur's collotype, without in any way giving an idea that was usually useful to the large professional printer. Briefly put, it consists of first sensitising the specially coated plate in a mixture of potassium bichromate and ammonium bichromate for five minutes, drying and drying in an oven or drying box. The box supplied with light now makes a drying oven at a temperature of 120 deg. to 150 deg. F. for from twenty to twenty-five minutes. Printing is done in a good pressure frame by the aid of a print meter. The bichromate is washed out and the print treated with a mixture of glycerine and water, this forming what is known as the etching bath. Ink is applied with a good printer's roller and take a pull, then from the pull mask, fix in position, and ink up and take the needed number of prints, it being only needed to occasionally treat the plate with the etching bath. The demonstrator went through the process from beginning to end, and passed round a large number of fine prints, some of which were printed during the demonstration by the aid of the ordinary office copying press.

## Commercial & Legal Intelligence.

**WESTERN CAMERA COMPANY.**—Ralph Winter Thomas, photographer and dealer, carrying on business at 69, Stokes Croft, under the name of the Western Camera Company, and residing at 28, Burghley Street, St. Andrew's Park, appeared in the Bristol Bankruptcy Court on Wednesday last. The gross liabilities were £740 4s. 3d., of which only £100 were secured. The deficiency was £419 10s. 3d. The Official Receiver observed that the petition in this matter was filed by a debtor, who was adjudicated a bankrupt on the 13th inst., in his own application. He states that he is 27 years of age, and has been carrying on business at the above address on January 1, 1905, without success. His largest trade creditor advanced him £200 to start with, which he purchased upon credit, at the sum of £238 18s., a photographic business, which had previously been carried on by his father. His liabilities comprise: Balance owing in respect of the business advanced from the father, and in relation to which bills were given and discounted, £127 15s.; balance owing to the trade creditor £100; £186 10s. 9d.; bankers' overdraft, £346 3s. (the bankers secured by the guarantees of the debtor's friends up to £350); accounts for goods supplied for the purposes of the business, £6d.—total, £737 0s. 3d. He states that his drawings from

the business have averaged £80 per annum. Mr. F. G. Tricks was appointed trustee, with a committee of inspection.

**LEGAL NOTICES.**—A receiving order has been made against Scott Stanley Meale, photographer, of Cottishall, Norfolk. The debtor has been adjudicated bankrupt.

A receiving order has been made against Alfred Ernest Priest, photographer, of 51, Sprowston Road, Norwich, carrying on business at 21A, Prince of Wales Road, Norwich. A meeting of creditors is announced for June 6 at the Official Receiver's office, Norwich.

## News and Notes.

**MR. SPEAIGHT'S MARBLE ARCH IMPROVEMENT.**—By the completion on Monday last of the great screen which separates the park from the immense piazza that has been formed at the Marble Arch, and by the opening of the park gateways to vehicular traffic, the work in connection with the Marble Arch improvement scheme is practically finished, for there remains now only some slight work to be done to the inside of the two park lodges which have been re-erected on their new sites just within the park railings.

Now that the whole of the hoarding around the screen has been removed, Londoners at last can appreciate the magnificent effect of this great improvement which has been carried out at the Marble Arch with such remarkable rapidity by the Works Department of the London County Council, who should be warmly congratulated upon their achievement.

The general character of the screen follows very closely Mr. F. W. Speaight's No. 3 design, with the exception that instead of the crescent shape he gave to his plan a straight line has been substituted by the authorities. It is understood that the Office of Works has been responsible for the architectural details of the stone piers, and general admiration has been expressed on their design. The actual length of the screen is no less than 450ft., and there has been some 300 tons of Portland stone used in its construction. The screen consists of twenty piers, the four flanking the Royal entrance measuring each 4ft. square and 18ft. in height, the ten piers that form the three public entrances into the park measuring 3ft. 6in. square and 16ft. high, and the six piers that divide up the screen proper are 3ft. square and 12ft. high. The magnificent gates for the Royal and public gateways in the screen, the design for which was recently exhibited in the members' tea-room in the House of Commons, will not be ready until July next, accordingly temporary wooden ones have been erected in their place for the present.

**THE LATE MR. E. G. BREWIS.**—Mr. Edward G. Brewis, photographer, New Bridge Street, Newcastle, died at his home at Warkworth last week. Mr. Brewis was a native of Gateshead, and in his youth was in the employ of Mr. Hay, who for many years carried on the business of picture dealer in Grainger Street, Newcastle. Afterwards Mr. Brewis turned his attention to photography, and started business in his native town; but he did not remain there long, and came to Newcastle, where he opened premises in New Bridge Street. He was fond of artistic pursuits, and was a prominent member of the Bewick Club. As a photographer he was often employed by the authorities at Armstrong College.

**THE INTERNATIONAL PHOTOGRAPHIC EXHIBITION in Dresden, 1909,** has just sent out its business schedule and notification forms in an edition of over 15,000 copies to the various societies and individuals in all circles interested in the work done by photography. These papers had been forwarded to the photographic industry as early as January last. The notifications from trade circles have already attained such a volume that the space in the large Industrial Hall provided for that purpose is almost all taken. The participation in the other classes will probably be of equally enormous extent, all the more so, as already numerous promises from scientific bodies and others interested in reproduction, professional and amateur photography have been sent in. As latest date for notifications in all classes August 1 of this year has been fixed. This exhibition is arousing great interest outside Germany. In some countries working commissioners are organising travelling societies to enable the exhibition to be visited to the best advantage. In the various German states

a travel fund has been arranged with great success, and there is a prospect of State or municipal support to these travel funds. For the information of the public reports are being made out on the contents of the exhibition, and these, together with explanatory lantern-slide illustrations, will be lent to societies interested free of charge. Information of all kinds can be obtained from the business offices of the exhibition, Neumarkt 1, Hotel Stadt, Berlin, Dresden-A.

**PHOTOGRAPHIC MANUFACTURE IN AUSTRALIA.**—"The Melbourne Age" writes:—Fresh evidence continues to be forthcoming to demonstrate the beneficial effects of the new tariff. Under the Kingston arrangement the duty on photographic material was, generally speaking, 15 per cent., but the Lyne proposals placed it at 35 per cent. against the foreigner and 25 per cent. against Great Britain. The rates, however, were reduced to 30 and 20 per cent. respectively, and with this protection Messrs. Baker and Rouse Propy., Ltd., considered they would be justified in making an effort to start a factory for the manufacture of articles used in great quantities by professional and amateur photographers, but imported from Germany and other countries. Mr. Baker at once sailed for America to make inquiries into the most up-to-date methods of production, and in the course of his investigations he has also visited England and the Continent. He is not expected to return for some weeks, but the firm has been advised that arrangements have been made for the establishment of a factory in Australia to produce many of the articles which are now imported. The works are to be situated at Abbotsford, and it is expected that the equipment will involve an outlay of at least £25,000. Machinery representing the most modern developments has already been shipped from Great Britain and the United States, and on arrival it will be installed without delay. Apart from its industrial aspect this departure will be greatly appreciated by those interested in photography—and they are to be numbered by the thousand—because it means that they will be always able to obtain absolutely fresh materials, a matter of extreme importance in regard to many of the articles in daily use, which are so liable to perish if kept for any length of time.

Mr. Baker has also been successful in negotiating with the largest manufacturers in the world for the production of the latest developments in photographic papers and goods, and amongst others he has secured the formula and rights for the manufacture of Kodak non-curling films, collodion carbon-paper, aristo paper, velox paper, solio P.O.P., and ferro-prussiate paper, and a new but well-known brand of dry plates. The firm has already established a reputation for Austral pearl paper, which is now largely used throughout the Commonwealth, and no effort is to be spared in the new enterprise to place reliable materials on the market. This extension of the field of industry in the Commonwealth is, as usual, meeting with considerable opposition from importers, some of whom have signed a petition to the Senate urging a reduction of the duties. German manufacturers, too, are making extraordinary concessions in the hope of being able to retain the trade in their hands. If they are successful, with the aid of free-traders in our midst, it will mean that the prospects of the new industry will be adversely affected to a very material extent, and that another avenue for the employment of our own people will be considerably restricted, if not altogether closed."

**NON-STRESS PAPERS.**—The Birmingham Photographic Co., Ltd., Stechford, write: With regard to our Non-stress Glossy Bromide Paper, your readers will be interested to learn that we have now succeeded in extending this particular advantage to the matt and silky surfaces also, so that all our bromide will be "Non-stress" in future.

**LONDON AND SOUTH-WESTERN HOLIDAY GUIDE.**—This well-known publication, now in its tenth year of issue, is in no way behind its predecessors in regard to the usefulness of either its letterpress or illustrations. It deals with the popular resorts, both inland and on the coast, which can be reached by the London and South-Western Railway, giving brief particulars of each which should prove useful to all classes of holiday-makers visiting the South of England, whilst the tourist will find valuable information as to the easiest and quickest routes from one place to another, including that part of Northern France which is accessible by the company's steamship

services. Several useful maps, lists of hotels, boarding-houses, and particulars of the various golf links in the district, form useful features of the book, which may be obtained, free, from Mr. H. Holmes, Superintendent of the Line, Waterloo Station, S.E., from any of Messrs. Smith and Son's bookstalls, for the price of one penny.

**LECTURES ON PHOTOGRAPHY AT THE ROYAL INSTITUTION.** The second of Dr. Scott's series of lectures was given on Thursday May 21, when the lecturer first dealt with the theories of development and fixing. To illustrate the reduction of stable salts of metal from unstable subsalts he experimentally showed the reduction of metallic copper from the suboxide, and afterwards demonstrated the action of the various fixing baths that have been employed, such as brine, ammonia, hypo, and cyanide fixers. The production of a Daguerreotype was then demonstrated, and a silver plate was sensitised, exposed, developed, and fixed before the audience, who were perhaps, rather surprised at the ease and rapidity with which the process was carried out. The plate was sensitised for one minute over iodine and then for ten seconds over bromide. After exposure of one minute to daylight under a negative it very quickly developed up over a dish of mercury kept at a temperature of about 60 degrees C., and it was then fixed in hypo. The lecturer then described the calotype, collodion, and albumen processes, and demonstrated the coating and sensitising of a wet collodion plate. The advantages of the grainless structure of the collodion image were pointed out, and some of De la Rue's collodion slides of the moon were shown on the lantern screen.

## Correspondence.

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### THE QUICK DRYING OF NEGATIVES.

To the Editors.

Gentlemen,—I notice in this week's issue of the "B.J." an article on the quick drying of glass negatives by the use of spirit formalin. I have used both methods many times and agree with the writer of the article that neither proves quite satisfactory. The milkiness sometimes caused by the spirit, as explained in previous articles in the "B.J.," and also the horn-like structure of the film produced by the formalin, certainly spoil the plates if after-treatment is required. The method I adopt when in a hurry is to wash the plate in two or three changes of water and then transfer it to an alum bath (3 to 5 per cent.) for about five minutes until the film is penetrated, which destroys all remaining traces of hypo, then wash in two changes of water to remove the bulk of the alum, surface dry, and stand up against the wall of the place, where the warm draught dries them very quickly. Dry-plates taken place quite as rapidly as by the methods mentioned in the article referred to, the time of washing is also shorter on account of the alum destroying the hypo, and the small quantity of hypo left in the film does no harm, as I have negatives made six years ago and dried by this method which are now quite as good as others dried in the usual way, and the film being harder still more rough usage.

I may add that, as the reason for the rapid drying of negatives is usually to enable one to make prints quickly, it is a good idea to merely rinse the plate after fixing and then press into contact with the film an old spoilt roll-film, with the gelatin removed, and print as if it were a dry negative, of course being careful that no hypo gets on the surface of the celluloid, which the paper comes in contact.—I am, yours very truly,

Glen Road, Wishaw, N.B.

May 22, 1908.

WM. MORRIS.

### THE LATE MR. BEN ILLINGWORTH.

To the Editors.

Gentlemen,—Please allow me through the "Journal," on behalf of myself, wife and family, to thank sincerely the Committee

Professional Photographers' Association, and all those friends out of the profession, from abroad and every part of the Kingdom, for their kind letters of condolence and sympathy, we have received, and are receiving, in the sad and unexpected death of my eldest son, Mr. Benjamin (Ben) Illingworth, who died of the same type of small-pox on March 28 at Neemuch, Central India. The disease was contracted in a travellers' bungalow at Nasirabad with Dr. Coomey, dental surgeon, of London, who also died same, several days after my son. My son, Dr. Coomey, and Reiffar were travelling India at the same time, and the latter who is a photographer, informs me that he evaded falling a victim of the awful disease through being called back to his studio and Higgins) at Mhow, C.I., owing to his partner being ill.

My letters are too numerous to be acknowledged individually, and all to realise through this source our great appreciation of the high regard my son was held in and out of his profession—I am, Sir, very faithfully yours,  
WM. ILLINGWORTH.  
Abington Street, Northampton.  
May 30, 1908.

## Answers to Correspondents.

*Matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.

*Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C.*

*For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. No unmounted copies of each photograph must be sent with the*

Wood (Mich., U.S.A.).—(1) Apply to Harold Hood and Co., Slide Works, Middlesbrough. (2) We do not think you will do in the way of exchanging photographs. You might try the one of one or two small advertisements.

The lens you name is a good one, but for the work you name could certainly advise you to have one with the larger aperture; the portrait aplanat, of the same maker.

ION.—See answer to "Ed. Plowman," p. 427, last week.

W.—You can prevent further infringement, but not penalise what has already occurred, by now registering the copy.

PE.—The enclosed are the best results up to the present I have been able to obtain by the Kallitype process, as explained "B.J.," date February 8, 1907. The great difficulty I find in getting a good black, and also in removing the yellow on paper made by the sensitiser. I have tried fixing in hypo ways, but have not yet got a satisfactory result. Can you give me any other details or formula whereby I can get good black and white pictures?—H. L. A. FOGDEN.

We have not tried Mr. Thompson's formula, but those given in B.J. Almanac," 1908, p. 832, will give perfect results. In case treble the quantity of citric acid in the developer should remove the yellow stain. The best developer for black tones is

sodium acetate ("B.J. Almanac," p. 833), which, as there directed, must be followed by a bath of 15 per cent. potass oxalate.

IGNORANT.—We cannot say. The regulations vary. Your only course is to inquire of the town clerks of the towns in which you are interested.

J. MILLAR.—The formula is quite suitable for bromide and other developed prints. For P.O.P. or C.C. you should neutralise it with a little solution of carbonate of soda, testing its neutral state with litmus paper. The paste, if properly made, resembles those you name.

COPYRIGHT.—I should be much obliged for you to give me information concerning copyright. I have a shop and make enlargements from any photographs brought in. A few weeks since a lady brought enclosed photograph to be enlarged. I enlarged same and exhibited it in my window. Some time after a gentleman came in and said he had taken the photograph, and had the copyright of it. He demands of me 10s. or the enlargement. Please say has the lady the right to have it copied for her own use. If not, who is responsible for it—myself or she? As I was ordered to enlarge it, not knowing it was supposed to be copyright, could I demand from that gentleman to see the copyright? I would be much obliged if you would give me all possible information.—PHOTO.

Unless the lady took the photograph herself it is not very likely that she is the owner of the copyright; she cannot be unless she paid the gentleman by whom the photograph was taken. The latter is quite within his rights in preventing you from exhibiting the enlargement, and both you and the lady who gave you the order are equally liable. We advise you to give him the enlargement, as this, we presume, is the cheapest way out of the trouble.

D. R. EVEREST.—Electric arc light is unquestionably the most efficient system. There are a number of excellent lamps—Westminster, Janus, Boardman, Jupiter. If you write to any of the firms, whose advertisements in our columns show them to supply requisites for professional photographers, they will send you information.

E. HUTCHINGS.—Certainly we should advise a reflex for a size like half-plate. A twin lens is very bulky. We advise you to get the "B.J." for June 14, 1907, which describes practically every reflex. The lens you name, or, better, one of the f/4.5 anastigmats, of about 9 in. focal length, would be very suitable for all-round work, though we should advise also a symmetrical anastigmat of smaller aperture, say, f/6.8, which is rapid enough for a large proportion of outdoor work, and does not require such careful shading from strong light as the lenses of larger aperture.

C. LANGRIDGE.—You cannot have anything better than a focal-plane folding camera, of which the Goerz-Anschütz is the best known example. See the advertisement pages of the "Almanac."

J. J. (Halifax).—We do not think insufficient washing alone accounts for the trouble. It is more likely that the combined bath was exhausted and was causing sulphur toning. This would continue further on the prints being placed again in hypo. We advise you to see that the bath is in proper working order and has a due allowance of gold for the prints.

BROMPTON.—I have been for some time trying to get a cold sepia tone on bromide prints, but have not yet been successful; the only thing I get is a horrible yellow colour. One of Wellington and Ward's representatives told me that in order to get a cold sepia I should expose my print so as to be able to develop the same right through; this I have tried, and I must say I have got a better result, but still it is not what I want. I am using Wellington and Ward's paper and canvas, and also using their formula for toning and developing metol hydroquinone.

We are not clear whether your query refers to sulphide toning or to the production of warm tones by development. If the former the subject has been frequently dealt with in our pages of late.

AUTOCHROME PLATES.—I am rather interested in colour photography, have been trying to get a really successful photograph, and was rather drawn to your remarks in the "B. J." of April 17, on p. 300 (part of a paper in Mr. Alfred Stieglitz's "Camera Work"). After reading it carefully and then trying the Rodinal developer, the picture came up beautifully strong, but on putting it into the reversal solution (permanganate acid bath) the picture washed off the plate. Though the film did not dissolve, the photograph disap-

r. Hollinger on keeping the show case changed. (P. 459.)  
patent for a screen-plate process has been taken out by Mr.  
ger-Shepherd. (P. 459.)  
"Times" contributor has published some useful details on the  
ing of a caravan for photographic pleasure or business. (P. 457.)  
n account of the present proposed legislation as to the sale of  
ons is given on page 447.  
he first of the four Bolt Court lectures by Dr. S. E. Sheppard. on  
chemistry of colloids is reported on page 452.  
new developer, said to be highly amenable to bromide, has been  
duced. (P. 447.)  
German magazine of photographic surveying has commenced  
lication. (P. 446.)  
err Novak has published a list of dyes suitable for the Traube  
chrome process. (P. 446.)  
ome notes on the construction of arc lamps having metallic cores  
ar on page 458.  
e draw attention to the fallacies to which the use of chemical  
ations in photographic research may lead. (P. 447.)

**EX CATHEDRA.**  
**Colour Photography and Crime.**  
The first instance to come under ore notice of the application of the Anne chrome process in criminology is; is ported from Middlesbrough. At a coroner's inquest tis-week a verdict of wilful murder was returned again man named Howroyd in respect of the death of a wosale on May 9. Evidence for the prosecution was largcid, based on articles of clothing worn by Howroyd whenalic was arrested, and alleged to be bloodstained, and, sons Drake-Brockman produced a number of colour pelled which revealed the presence of bloodstains on the aas the, in question much more clearly than the marks we The, cernible on the articles themselves. These photexceed- were made on Autochromes, of his work in which I really- Dr. Brockman exhibits a number of specimensfault, as present Colour Society's exhibition.

**Colour Transparencies by Artificial Light.**  
A point deserving of notice in salts of to the exhibition of the Society of potash Photographers now being pty. In the "B.J." Offices is the device of the new overcoming the too yellowish light which is g w Bill treats the Osram lamps specially selected for ite of potash Messrs. Sanger Shepherd, for the illumination transparencies, filter the light through a pal-Bill that will In the case of the table frames of Autoch's beyond what Shepherd, and pinatype transparencies a sinew developing been obtained by using pale blue paper Bichromate of of the light from the incandescent lamps. curred from its was first used, but the change to blue, m'ces are alluded after the opening of the exhibition, has ficial that one may suggest the commerciahing, in the new spectroscopically adjusted for use, say, wotography, even gas and electric light. Illumination by iness now before most practical method for showing nuas to whether it chromes, and such a paper might be rdoes it will come should think, for the use of colour worYear.

**Exhibition of Balloon Photographs.**  
One result of the grv restlessness energy with ATION AND prosecuting the studIONS. balloons and air-ships is the exhibitie misuse of chemical graphs which is to take place at Beaver use as an aid to this year. A large number of well-b out of place. intimated their desire to show theairation into a chemical exhibition promises to be of great voted to the collection popular interest. Doubtless this isbe closely observed, and tions of the kind ever held. We irefully noted, while any of the photographs taken from thothers should be checked. Count Zeppelin in the neighbourhteresting and wearisome stance. These are of more to process must be repeated

best, yet they impress upon one the fact that balloon photography opens out a new sphere of influence and usefulness for photography. There can be no doubt that the long balloon photographs will be in great demand all military authorities, and though they are not likely to take the place of ordnance maps, they will prove indispensable supplements to them.

\* \* \*

**Chemical Effect of Light.** A paper, by Dr. G. J. Fowler, on some observations on the chemical effect of tropical sunlight, read before the Manchester Literary and Philosophical Society, contains some interesting information with respect to the power of the light in the tropics. The highest record obtained was on the sea, in the vicinity of the Arabian coast in latitude  $16^{\circ}$  and longitude  $54^{\circ} 8'$ . Here the photo-chemical intensity of the sunlight was forty-two times the record for a bright, dry winter day in Manchester (whatever that may be), three times the highest summer record for the same day. If we remember how powerful the light can be in our own climate in favourable conditions, it is clear that three times a high record means a great deal. It is, however, to be remembered that the comparison is between a sea record and a land one, and the difference between the power of the light on sea and on land is very great indeed, even round our own coasts. The land records do not seem to differ so much, as it is reported that the European localities give very high records, and Trentesina has even been known to excel Calcutta.

\* \* \*

**Royal Observatory.** Wednesday, June 3, was the annual visitation day at the Royal Observatory, where, and the usual crowd of visitors attended to the daily work of the instruments, study the photographic records, and discuss chocolate and cracknels at all in the buildings and grounds. They also had a factory of becoming personally acquainted with the rather attenuated condition—through the big make is. The report does not contain much on the work of the photographers except the fact that the negatives of the eighth satellite of Jupiter was Melotte by the inspection of a photograph on Sunday, February 28, and it was then confirmed by previous photographs and by securing later where possible and April.

\* \* \*

**Sunday.** I, a writer in an American magazine lays way possible a great deal of stress on what he calls lady retouch a stereoscopic effect obtainable on the attends the of an ordinary single lens camera, but it is unlawful to argue from theory only and not in the case. The theory is that, as every point in work on Sunday is argued by a conical beam of light, which to—at present by the focus towards the observer, therefore heard that the two eyes to obtain two distinct reference to the, and, consequently, a stereoscopic Under the old, This is all very well on paper, but in sometimes applied. This is the projected image at the distance in calling on Sunday, the projected image at the distance Act, for you to at our "near point." Taking this from the Sunday, it is impossible for any cone of light which it is illegal at once unless its angular aperture Sunday. But that of  $f/8$  is the absolute minimum If you refer to p. 68 of ten inches and infinitely distant will find an article commonly use a distance of about affects photographers. can be no parallax effects unless Parliament—not yet view, the conditions only prevail will be made with reference. If we study the inverted real adding lens we can get the effect I show that there is no sugges-

tion of stereoscopic relief. Two confused images are seen and their various points can only be combined with a considerable effort. The result is by no means realistic and it has a far greater resemblance to pseudoscopic than to stereoscopic effect. In the camera the effect can only be produced in out-of-focus parts of the image, and it cannot be seen clearly except with a clean glass focussing screen. With a ground glass screen the image that we see is on the screen, the scattering effect of which enables both eyes to see all parts. This is a plane image and therefore parallax, and so-called stereoscopic effect disappears altogether.

\* \* \*

**A Journal of Photogrammetry.** The scientific application of photography to surveying, the literature of which now runs to a very fair number of volumes, is at last to have a periodical publication to itself in the shape of the "Internationales Archiv für Photogrammetrie." This magazine is to appear monthly under the editorship of Professor Eduard Dolezal, of Vienna. The first number includes an appreciation of Colonel Laussedat and of his labours in establishing the science of photogrammetry, and an editorial article on photography applied to the record of monuments. Dr. N. Herz writes on the perspective representation of non-parallel surfaces, and Dr. R. Thiele contributes some notes on metrophotography by means of a kite. The "Archiv" is published by Carl Fromme, 2, Glockengasse, Vienna II.

\* \* \*

**Examination for Cinematograph Operators.** A prospectus of the examinations arranged jointly by the Cinematograph Manufacturers' Association and the Northampton Institute reaches us from the secretary, Mr. J. Brooke Wilkinson. It informs us that the second examination will take place on June 29 and following days; it reprints the questions asked at the written examination already held, but it does not tell what we should very much like to know—namely, the number of candidates at the first examination, and the proportion who have been placed upon the register of certified operators. Admirable as such an examination scheme is, our fears of it from the first have been that the thoroughly efficient man would not think it worth his while to pay the examination fee of ten or fifteen shillings, and that therefore all the examination could achieve would be to certify the just passable men and refuse certification to the unfit. We shall be glad to hear, however, that our fears were unfounded.

\* \* \*

**Diachrome Toning.** Dr. A. Traube's process of replacing the silver image by a dye with the aid of a solution which first converts the image into silver iodide has already been described in our pages, and not long ago we were able to report on the preparations issued by Perutz, of Munich, for the process, which, for producing rich warm tones on lantern-slides, is an excellent one. Dr. F. Novak now, in the current "Photographische Korrespondenz," mentions one or two dyes which he has found to act effectively on the image of the lantern-slide or transparency which has been bleached in, say, a solution of iodine in potassium iodide. Among these dyes are: methyl green, brilliant green, Turkey blue, rhodamin B, chrysoïdin, methylene blue, malachite green, crystal violet, and auramine. Solutions of any of the above are made in water—the strength is not very material—and the bleached slide allowed to soak until of full intensity. Basic dyes are best for the process, as a weak bath of acetic acid completely clears the gelatine of them. The slide can be left with the silver iodide in the film or the

ter fixed out, for which latter purpose some tannin and sodium acetate should be added to the ten per cent. hypodermic solution in order to fix the basic dyes.

\* \* \*

**New Developer.** Dr. Georg Hauberrisser, in the current issue of "Photographische Korrespondenz," describes a new substance named Pyramidol, said to be the makers, the Brugg A. G., to be a chemical compound of hydroquinone and paramidophenol. As regards the development, there is not much to choose between Pyramidol and the mixture of its constituent bodies, but Dr. Hauberrisser states that in suitability for dealing with over-exposures by the addition of potassium bromide, the new developer is of quite exceptional character. A suitable formula is:—Pyramidol, 15 grains; soda sulphite, 10 grains; potassium carbonate, 160 grains; water, 7 ounces. This, with a normal dose of bromide, developed a correct exposure in four minutes, whilst another plate which had received sixteen times the correct exposure was treated with the same solution dosed with four times the bromide. Development took nine minutes, and gave a negative in every way as good as that correctly timed.

### THE PROJECTED POISONS ACT AND PHOTOGRAPHY.

The House of Lords clearly take great interest in the safety of the public in so far as the sale of poisons and poisonous substances is concerned. Each year—for the last four or five—Bills have been introduced to amend the Poisons and Pharmacy Act of 1868—the one now in force—but they have not become law. This year a fresh one (as intended by the select committee) has been brought in, and was printed and issued to the public a couple of weeks ago. It is entitled "An Act to regulate the sale of certain poisonous substances and to amend the Pharmacy Acts." Many of the substances employed in photography are of a more or less poisonous nature, and two or three of them deadly poisons, it is not altogether surprising that some dealers in photographic requisites, more particularly professional photographers in country places, who sometimes supply amateurs with small quantities of chemicals, may be a little concerned as to how any new law relating to the sale of poisonous substances may affect them. Recently we have received several queries on the subject from different correspondents in the country, and therefore, for their information, we may point out the present situation.

The first clause in the new Bill reads as follows:—"Schedule A to the Pharmacy Act, 1868 (which specifies the articles to be deemed poisons within the meaning of that Act), is hereby repealed, and the schedule to this Act shall be substituted therefor." On comparing the two schedules we see that all the bodies mentioned in the 1868 Act are included in the new Bill with several additions. These latter, with one or two exceptions, are but remotely connected with photography, though mercuric iodide and mercuric sulphocyanide are certainly "photographic chemicals." In the 1868 schedule corrosive sublimate is named and in the new one is also included, with the addition of "preparations of corrosive sublimate." It would therefore be illegal to sell any solution or preparations, frequently used for the intensification of negatives, unless the vendor is a certified pharmaceutical chemist. It is a little strange that in the old Act, as well as in all the projected Bills for its amendment, the antiquated name, "corrosive sublimate," is still retained for bichloride of mercury.

The second section of the new Bill repeals a portion of the old Act, so that it does not now restrict to pharmaceu-

tical chemists the sale of poisonous substances containing arsenic, tobacco or alkaloid of tobacco for use exclusively in connection with agriculture or horticulture if the person so selling them is duly licensed for the purpose under this section by a local authority and conforms to any regulations as to the keeping, transporting, and selling poisons under this section. Hitherto the sale of these substances has been confined solely to pharmaceutical chemists, and the Pharmaceutical Society has at times prosecuted seedsmen, ironmongers and others in agricultural districts for selling weed killers, sheep dips, etc. It will be noted that a licence to sell these bodies will be required from the local authority, and part 2 of this section enacts that, before granting any licence, the local authority shall take into consideration the reasonable requirements of the public in the neighbourhood. It will thus be seen that the local authority will have the power to withhold a licence if it thinks fit.

In the case of pharmaceutical chemists having more than one shop, and in the case of branches of companies, there must be conspicuously exhibited on the premises the name and qualification of the person by whom the business is conducted. This to most persons will appear a very satisfactory regulation.

Section 5 of the Bill relates to restrictions on the sale of certain mineral acids. Those named are sulphuric acid, nitric acid, hydrochloric acid, and soluble salts of oxalic acid. It will not be lawful to sell any of these poisons unless the vessel containing them is distinctly labelled with the name and address of the seller, as well as the name of the substance, and the word "Poison." The penalty for infringement of this section is a fine not exceeding five pounds. This is a very reasonable and really necessary restriction with which no one can find fault, as so many accidents have happened through vessels containing these poisons not being duly labelled as to their contents. It will be noted that among "soluble salts of oxalic acid" is included the neutral oxalate of potash which is somewhat largely used in photography. In the Schedule A of the 1868 Act, and indeed that of the new Bill, oxalic acid only is mentioned, but the new Bill treats all soluble oxalates as poisons; hence oxalate of potash will have to bear a poison label.

After all there is not much in the new Bill that will materially interfere with photographic dealers beyond what is done by the present Act. Nearly all the new developing agents are poisons, so is pyrogallol acid. Bichromate of potash, too, is a poison, and deaths have occurred from its being swallowed, but none of these substances are alluded to in the Bill.

Taken altogether there is little, if anything, in the new Bill that will cause inconvenience in photography, even if it becomes law; but with the mass of business now before Parliament it is a little problematical as to whether it will be passed at all this session. If it does it will come into force the first day of January next year.

### PHOTOGRAPHIC INVESTIGATION AND CHEMICAL EQUATIONS.

SOME time ago we commented on the misuse of chemical equations, and a note on their proper use as an aid to investigation may, therefore, not be out of place.

The first stages of an investigation into a chemical photographic process should be devoted to the collection of facts. The process itself must be closely observed, and its various features and phases carefully noted, while any observations made previously by others should be checked. This is, perhaps, the most uninteresting and wearisome part of the investigation, for the process must be repeated

many times so that one may be able to distinguish between characteristic and accidental effects. Further, it is necessary to try every variation of the process that can be thought of, even though one may feel confident that many of the possible variations can have no effect at all. The very fact that the process has not been satisfactorily explained before shows that some minor matter has been overlooked, hence we cannot afford to neglect any details.

At a certain stage what appears to be a clue is struck—one that is sufficiently probable to enable the worker to build up a theory. If this theory is correct then certain reactions must take place, and if these reactions really occur then they must do so in accord with this or that equation. With a little arithmetical juggling it is possible to explain anything by an equation, and with a little knowledge of chemistry it is generally easy to get a considerable amount of plausibility into several different equations. The next process is to test these equations and find out whether the products that they suggest should be formed can be found and identified. If they can, the next step is to test whether the reactions tried are sufficient to explain everything that has to be explained. If these tests fail then we must try back. It is necessary to build up some more theories on the original clue, and if they all fail, to go back still further and look for another clue. Chemical equations are thus useful to the investigator as aids to the testing of a theory. They are not proofs, for the mere fact that the two sides of an equation are equal to one another means nothing. It does not show that it is correct, for an untrue equation will "equate" just as well as a true one.

At the end of the work it should be possible to describe by equations what reactions occur, provided every detail has been proved; but, in photography, we know so little with regard to the fundamental material that we employ that any very definite result is seldom reached. Some processes are conducted upon the latent image as a foundation, others upon a "printed-out" image, and some upon the developed and fixed image; but in none of these cases do we know precisely the nature of the image upon which we are working. We have to form an hypothesis somewhere and work upon this as a basis, hence the expression in the shape of formulæ of the reactions that occur is

nearly always deceptive. Such empirical formulæ have uses to other investigators, but they are very apt to deceive students who have not arrived at the stage of discreet scepticism of the mature worker, hence should never be given without a note of warning.

Another fact that renders it almost impossible to arrive at true final equations in photographic work is the peculiarly obscure nature of many of the compounds that one meets with. In many processes some one or other of the obscure brown oxides of chromium is met with. There are such doubtful compounds that it is not even easy to say that they are oxides. In the case, again, of sulphide toning, an article by Mr. Carnegie that we published some time ago showed that the final brown image is a so-called compound of silver sulphide and gelatine of a very unusual nature. Such soluble sulphide compounds are in no means well understood, and the formation of an image expressing the effect of sulphide toning is therefore at present a task beyond the ability of the most competent chemist, though it is probably often tackled without hesitation by the amateur. Then, again, in the majority of photographic processes we meet, sooner or later, with the use of the mysterious photo-haloid silver compounds described by Carey Lea, but not yet understood by any one, and in all probability we encounter also other apparently analogous compounds which neither Carey Lea nor any one else has described. In fact, at the end of a photochemical investigation the investigator is generally more or less in a state of melancholy bewilderment. Instead of writing equations that will describe all he has found out he is more probably wondering when he will learn something about the silver halides, and when he will understand gelatine.

The use of equations as a chemical shorthand means of describing known and proved reactions needs no comment. Without them chemistry would be an impossible science, but the misuse of speculative empirical equations should be carefully avoided. Though sometimes used as speculative bases of argument and experiment they are very frequently deceptive, even to the user, for often a very expert chemist can tell the difference between a probable and a quite impossible equation, and much may be wasted in testing impossibilities.

## THE PARIS PHOTO-CLUB SALON AT THE VOLNEY ART CLUB.

THE opening of the French Salon has, unhappily, been announced too late for the usual foreign contributions. Most of the English pictorialists found themselves unable to respond at such a short notice to the special invitations sent by the Photo-Club Committee. Consequently the list of the English workers represented at the Paris Salon is small, and comprises very few invited guests. We find in the catalogue the names of Mr. Bagot Molesworth, Miss Baird, Mrs. Barton, Miss Caswall Smith, Messrs. Cocks, Croke, Dudley Johnston, Gear, Job Latham, Staddon, Miss Stevenson, Miss Warburg, Mr. J. O. Warburg, and Messrs. Warner and Wickison.

Other countries are represented as follows:—America, by Miss Buermann, Mr. Coburn, Mrs. Käsebier, and Mr. Steichen. Holland, by Messrs. Arendsen, Boer, Brok, Eilers, Huysen, Idzerda, De Jonge, Kauffmann, Loeb, Lons, Navta, and Meinberg. Belgium, by Dr. Cardyn, MM. Gaspar, Geerts, Tekx, Misonne, and Van der Aa. Germany, by R. Dührkoop, Fischer, Professor Van Jan, Baron de Meyer, and Welcker. Austria, by Dr. Mikolasch.

The only oil prints in the English collection are those we kept

over from the preceding oil-process at the Paris Photo-Club's rooms. Mrs. Barton, Mr. Job, Mr. Croke, and others are still faithful to the carbon process. Platinotype reigns supreme amongst Americans, though some of them use a dash of gum on the top. The lemon-peel of the national style of close framing and December fog effects. These frames are meant to set off the heavy grained style of sombre print—a liberal coat of varnish. But what would the walls of the exhibition room look like with rows of such funereal squares about?

On the contrary, Baron de Meyer and Mr. Coburn have adopted the actual French style of framing, with a pale or white wood-baguet and cream coloured or Japan tinted mounts.

Mr. Steichen either frames close or uses a rather elaborate mounting scheme, though lighter than his picture. His style of work can well stand it.

I admire Mr. Coburn for the honesty with which he adheres to his principles. This year his large pictures (Notre Dame

pted) undoubtedly show no signs of personal intervention ; Mr. Bernard Shaw will have cause to rejoice. On the other hand, let us discreetly accept the legend of the ichen straight print ; it soothes the feelings of the Secession- ists, and does not disturb Mr. Steichen in the least. His six- ictures, either because he has or has not intervened, are- erb, and have deservedly been given the centre of the- icipal panel between Mr. Coburn and Baron de Meyer, who- some very fine work that has already been hung, I believe, the Meyer-Coburn exhibition lately. The prominent exhibitors of the French section are the same- have kept the foremost rank for the last five or six years— a few desertions—such as that of M. Grimprel, for example. ew promising pictures may be found by comparatively new- ickers, such as M. Billard, Mdle. Milton, and M. Poson- ; but nothing decidedly striking arrests the eyes of the- tors outside the work of Puyo, Besson, Dubreuil, Le- ue, Hachette, Bergon, Mdle. Laguarde, and a few others. ne thing may be said against the French school. Its average- of picture is too small for a big room like the Volney's.

De Meyer's frames, which looked quite huge when the panels were being composed on the floor, are just the right size, but not more, when on the wall. But this is rather a dangerous question to bring up. What would the Salon hanging committee say if all the exhibitors presented their whole-plate pictures surrounded by frames twice and a-half as big as the print? Two rows of such big frames are all that could be placed over a cimaise, and then the second row will be high ; a third would result in skying, with the usual consequences—a bad time for the hanging committee on the day of the "Vernissage."

In favour of the French school, I will say that at every succeeding Salon it shows a marked progress in the rendering of values. And this is especially interesting to note when it has become the fashion in other circles to scoff at the time-honoured principles that have for centuries been followed by the very first artists in black and white.

I sincerely wish I could feel as many pictorialists do, or pretend to, on this same subject. It would save such a lot of study, trouble, and disappointment.

ROBERT DEMACHY.

## THE EXHIBITION OF COLOUR PHOTOGRAPHY,

step taken by the Society of Colour Photographers' in hold- a second exhibition, has been generally approved by those- have visited 24, Wellington Street. As mentioned- er "Ex Cathedra" the illumination of the autochrome and- er transparencies by reflected light has been improved by- ing a pale blue paper from which to reflect the light of the- am lamps. The latter alone is palpably too rich in yellow- red, the effect of which depresses, in particular the proper- dering of the greens. This applies equally to all kinds of- isparencies, but the use of the blue paper has given a very- ch improved rendering. Before quoting some opinions of the- ss on the exhibition, attention should again be drawn to- fact that the exhibition remains open daily until June 27,- 10 a.m. to 8 p.m. (Saturdays, 10 to 5). A charge of six- pence admission (which includes a catalogue) is made by the- ety.

he "Times" says: "Some of the still-lives, like those of Mr. ry J. Comley, and the flowers of Mr. Samuel Manners, are- sing. Mr. E. A. Burchard imitates impressionist water-colour- essfully, and enjoyable things are sent also by Mr. Theodor Heuss, C. Donaldson, and Mr. W. L. Bayley, while the Rotary Photo- ropic Company exhibit some vivid portraits."

he "Westminster Gazette" states: "Though only six months- e elapsed since the first exhibition of the Society of Colour Photo- ographers, yet there is a very marked improvement in the quality- he work. No new processes are shown, but the older ones are- ently becoming better understood and more completely mastered- her exponents. Some prints by Mr. Samuel Manners, according- he catalogue, are by a "process not stated," but look remarkably- examples of the autotype process, brought to a very high state- erfection. Here, in our opinion, we have the gems of the whole- ection. The colouring is perfect, both as regards truth and the- acy of the gradation, while the detail and the drawing are such- an only be produced in the camera."

he "Morning Post" says: "Mr. Comley displays several excel- examples of his tri-carbon prints, and Mr. Samuel Manners shows- e exceptionally neatly rendered flower and fruit studies; one of- best purely imitative prints on the walls being this exhibitor's- iles" (No. 68)."

The "Daily Telegraph" states: "One may here compare examples- of the following processes—viz.: Three-colour carbon, pinatype, Uto- bleach-out paper, Sinop, bichromated size and pigment, Autochrome, and Sanger-Shepherd. The worker in his anxiety to exploit the- colour rendering powers of the process, selects objects showing bril- liant colour. Possibly just at first these bright pictures may catch- one's attention on entering the rooms, but after a little time the- quieter subjects commend themselves by their force of simplicity."

"Nature" remarks: "The application of Autochrome plates to- photomicrography is well exemplified by Drs. O. Rosenheim and H. R. Hurry. These gentlemen also show photo-micrographs of the- starch grain itself, and the area of the black filling between the- coloured grains is larger than one would have expected, probably- larger in the particular plate photographed than in many other- plates."

The "Pall Mall Gazette" writes: "It is a most interesting show; not, perhaps, because of any strikingly novel improvements with regard to processes, but rather by reason of the suggestions which such an exhibition as this must make to the photographer as to the course of future progress. The general standard is high—a good deal higher than last year—if everything be taken into considera- tion. There is an encouraging tendency to abandon such subjects as those made up of a couple of dozen of the most brilliantly coloured objects the photographer could collect from house and garden, and to aim rather at the pictorial representation of land- scapes and figure subjects. This, of course, is a great move in the right direction, a move absolutely necessary if colour workers are to combat the view of the sceptics to the effect that colour photo- graphy, while providing most useful records and descriptive docu- ments of the objects represented, will never satisfy the require- ments of the artist. The pigment films supplied by the Rotary Company are evidently very popular. The Secretary, Mr. H. J. Comley, is easily first for work by this process. After a long pause at the 'cucumber, orange, and blue tablecloth' stage, he is progressing in the right direction, and his landscape work shows considerable promise. Some of the best work shown is that by Mr. S. Manners, who probably has very good reason for not stating the process used; the colours are certainly excellent, and are never violent or crude."

ESSRS. RAINES AND Co. have just added to their well-ordered- izing and printing works at Ealing, W., a new building specially- apart for carbon work. This separate department includes two- x-rooms, each 40 feet long, and allows Messrs. Raines to deal

on any reasonable scale with a process in which they have for years- past been regularly turning out most excellent work. Their greater- accommodation will thus allow them to retain their standard of- quality while dealing with the largest orders in carbon.

## BRUSSELS—THE VENUE OF THE PHOTOGRAPHIC CONVENTION.

MEMBERS of the Photographic Convention of the United Kingdom have doubtless read the official handbook, perhaps have studied Black's "Belgium," or the better Baedeker's "Belgium," yet I doubt if they have gained an impression of the Belgian

that is, the south-east quarter of the town—is THE essential part of Brussels. The ground begins to rise steeply as it goes (eastward) across the centre red line which crosses the map. The old streets, the "Grande Place" (which is the

In Wauxhall Park, Brussels, close to the Headquarters of the Convention.

*Photographs by G. E. ...*

capital, where, under the presidency of Sir Cecil Hertslet, the Convention meets from July 6 to 11. It is not easy for a guide-book to give a general impression of a big city: the detail, as in many a photograph, overpowers the essential features. Until a week or two ago I was in the same position. I had read the guide-books, studied the articles of MM. Vanderkindere and Delevey in the handbook, hung over the map of the city, but still had a hazy idea of how, as a Conventionier, I should quickly become familiar with the parts of Brussels most worth seeing, and how I should use the really few hours which are left over to the Conventionier from the official programme of papers and excursions. Therefore, finding myself in Cologne with twenty-four hours to spare on the way back to London, I made a small detour from the direct way to Ostend, and spent a day and a night gathering a first impression of what Brussels is like. The map of Brussels in the Convention Handbook shows the town proper—that is to say, that enclosed by the broad green boulevards, which are the glory of Brussels. Run the finger from the Gare du Nord (A2) to the Gare du Midi (D4) and you get a convenient base line of division across the city. This line commences with the Rue du Nord, continues as the Boulevard Anspach, and ends in the Boulevard de Hainaut. A horizontal line across the map runs from north (on the left) to south (on the right), so that our base line runs from north to the south-west. The part of the town above the Boulevard Anspach on the map—

of Old Brussels), lie below this line on the map (i.e., south). The ramparts, the modern art galleries, royal palaces, Palace of Justice, and other Government buildings—all very imposing—stand at the top of the hill up which one ascends

Garden Restaurant, Wauxhall Park, adjoining the Headquarters of the Convention.

such streets as Rue de la Montagne, Rue de la Madeleine, Rue de Ruysbroeck. The electric cars, following the longer and more picturesque route of the boulevards, take one quickly from the lower to the higher town. As the railway stations are at the bottom, and the "Cercle Artistique," the headquarters of the Convention, at the top of the town, it doesn't matter much to one's hotel is, so far as avoiding the hill climb is concerned. The lower town is, of course, the business part and

Those beautiful old buildings, the Hotel de Ville and Hotel du Roi, looked down on hundreds of market carts from the country, ruddy farmers and peasant women, and the buyers of fruit and vegetables. The market spreads through a narrow street to either side of the Stock Exchange, and even out into the Boulevard Anspach. The countryfolk have been there for goodness knows how long: scores of their dogs, tied to the carts and barrows which they have pulled to the market,

The Park of Wauxhall, Rue Royale, Brussels. The Headquarters of the Convention are in this Park.

noisier. Going back to the Convention map, the visitor can take it that within the area included by our line (between the two railway stations) and the Boulevards in Botanique (A2), Bischoffsheim (B1), Du Regent (C1), Du Midi (D2), and Du Midi (D4) are to be found the sights of Brussels. The parks in the suburbs are very charming, but I am speaking now of the city itself.

make a babel of canine conversation. . . . . Towards eight o'clock there is a move. The dogs are reharnessed, the vendors rapidly disperse, the last few laggards are hustled away by a quiet hint from the police, and before the last cart has turned the corner of the Grande Place, a small army of sweepers is at work, and a minute or two later all is tidied up for the flower merchants, who arrive about nine to take up

Verandah and Garden of the "Cercle Artistique" where the meetings of the Convention will be held. The "Cercle Artistique" is in the north-east corner of Wauxhall Park.

They tell you Brussels is a miniature Paris, but it accomplishes all that a great metropolis achieves, because, though it is small, it makes good use of its space. In the busy centres of the lower town one must be on the alert to keep up with the city's kaleidoscopic movements: Brussels is a veritable change artist. For example, at six in the morning the scene in the Grande Place just behind the Exchange (B3).

their quarters for the day. On Wednesdays the Stock Exchange meets, and the steps of the Bourse, which an hour or two before were littered with rhubarb stalks and vegetable debris, are peopled with smart, frock-coated gentlemen, who pause from business to take an occasional bock or light déjeuner at the innumerable cafés in the Boulevard Anspach. I don't know about Paris in miniature, but the scene, as I saw it in its

phases, was like Covent Garden Market put down outside the Mansion House, with the Dogs' Home from Battersea transplanted to the corner of Threadneedle Street.

A place to linger in at any hour of the day, when one has a camera, is this corner of Old Brussels, the Grande Place. Nowhere else in Brussels is there its equal. The palaces of the upper town are splendid buildings, but do not approach the beauty of these examples of mediæval architecture. Next to them in point of attractiveness to the stranger are the boulevards—not the Boulevard Anspach and other boulevards of shops and restaurants, but the the avenues already mentioned as completely encircling the town. The hilly position of Brussels makes it a tiring place if one keeps on the move from one part to another, but the boulevards afford the most delightful relief from the noise and heat of the streets. The shade and coolness of the country, accessibility to varieties of refreshment, a ceaseless procession of les Bruxelloises, as well dressed as any women in Europe (if a little loud to English taste)—can tired and thirsty man desire more than this? Pres-

suming he does, then I can lead him to it. In the Waux Park (B1 and C1) he will find a still more pleasant retreat of miniature Park of Versailles, with only the so of a passing electric car to compete with the splash of the fountains, and near at hand, as shown in second photograph, a restaurant-garden, where every evening in the summer a band plays, and the visitor can experience the enjoyment of a scene which England can rarely offer him. Unfortunately, my photographs can only suggest the appearance of the garden in the evening when thronged with people. This garden, the coolest and most delightful spot in all Brussels, adjoins the club of the Cercle Artistique where the meetings of the Convention are to be held. I have been privileged to be in the confidence of my friend Br in many Convention matters, but the one thing he has told me is how he proposes to entice members away from Park of Wauxhall and its orchestral wine-garden to the evening meetings of the Convention. I suppose he doesn't know.

G. E. I

## THE CHEMISTRY AND PHYSICS OF COLLOIDS.

[The following is the text of the first of four lectures now being given by Dr. S. E. Sheppard at the L.C.C. School of Photo-Engraving, Bolt Court, Fleet Street, on Thursday evenings at 8 o'clock. The syllabus has already been published in our pages, and, by courtesy of the lecturer and of Mr. A. J. Newton, the Principal of the Bolt Court School, shall publish the succeeding lectures.—Eds. "B.J."]

THE specialised study of colloids and the word "colloid" itself were introduced by Thomas Graham. In his fundamental investigations on the diffusion of dissolved substances (Phil. Trans., 1861, p. 183) he draws attention to the great difference in properties between easily crystallisable bodies, such as salt, sugar, etc., and bodies such as gelatine and albumen. Whilst the former diffuse rapidly and pass with ease through animal membranes, the latter diffuse very slowly, if at all, and cannot pass through membranes. Graham went so far as to speak of two different worlds of matter, the crystalloid and the colloid. We shall see that subsequent investigations have shown that here, as elsewhere in nature, unity of phenomena prevails, and that transition stages exist which do not allow us to contrast so absolutely these apparently opposed states of matter.

Before dealing with particulars, let me put before you some points indicating the far-reaching importance of colloids in the arts and industries, and, above all, in life itself. Briefly, it may be said that all life processes take place between bodies in the amorphous or colloidal condition. Hence the exact investigation of this condition is of quite special importance to the physiologist and biologist, and in consequence it is to them that we owe much of our present knowledge in this borderland of science. But (of the importance of colloids in technics and industry) much besides. Here are some of the industries more or less dependent on the chemistry and physics of colloids:—The manufacture of earthenware, porcelain, and so forth, and of ultramarine; the iron and steel industry, for we know now that the principal varieties of steel are colloidal solutions in iron of certain additions, principally carbon. Again, coloured and milk glass, enamel ware, and rubber goods—you will see that I am already drawing nearer to photography—tanning and dyeing, are industries whose scientific bases must necessarily be of importance to the scientific photographer. Paper, the general groundwork for your art, is a colloidal substance, and the coatings you put upon it, the processes to which you submit it, are colloidal, too. That being so, it may well be asked, what is the exact definition of "colloid"? A certain maxim has it that distinctions are invidious, not to say odious. It is, however, the business of science to distinguish and define, in attempting which she is constantly met with the continuity of natural

phenomena, which refuse to be shut up in watertight compartments. Hence our classifications are at the best provisional and this applies especially to the subject in hand.

### Solutions and Colloidal Solution.

Before attempting definitions and classification for the colloid state, I must ask you to briefly consider prevalent notions of the nature of solutions. In a solution of, say, salt and water we have evidently a very intimate mixture of the components. We express this by calling it a *homogeneous* mixture, meaning that the smallest portions we can divide it into show the same properties as the mass. Such a mixture under the highest magnification with the microscope shows no resolution. I believed that the salt exists in the solution in its ultimate molecules, too fine for our present extension even of the sight sense to perceive. The properties of the solution, however, may be predicted from its components, whilst in a chemical combination a new body arises, with new and distinct properties. Here also closer investigation shows that the passage from solution to chemical compound is only one of degree. As stated such a solution the salt moves freely or diffuses; to the extent, however aided, the solution appears clear. But I have heard of a "solution" which shows practically no diffusion, and is yet clear by transmitted light. Faraday and, following him, Tyndall showed that on projecting an intense beam of light through such apparent solutions as the "purple of Cassius" the path of the beam became illuminated, the scattered light at the same time being polarised (distinction from fluorescence). This method of demonstrating optical inhomogeneity is not, however trustworthy, as, owing to its great sensitiveness, small quantities of dust may lead to false conclusions. Still, the majority of "colloidal" solutions may be roughly recognised by this means. It must be remembered that no particles can be seen with the microscope. We know that very fine powders form suspensions, in which the particles are microscopically visible. These differ from colloid solutions or hydrosols as follows:—

### Hydrosols.

(1) The much finer state of division of the colloid particles, presenting an enormous free surface.

By definition, a suspension—a two-phase system—the

of which are less than  $< 1-4,000 \text{ mm.} = .25 \mu$  is a solution.

average molecular size reckoned as  $.2 \mu$  from kinetic gas theory.

$\mu$  = limit of microscopic resolution. Hence between limits lie colloid solutions.

250  $\mu$  . 0.2  $\mu$

The next difference is the irreversible nature of the coagulation produced by electrolytes. Ordinary suspensions give the state on re-shaking up. Coagulated colloids do not.

Colloids are strongly absorbed by porous bodies such as coal. I shall return to the nature of absorption later, as of fundamental importance in photographic processes.

Colloids in solution react with each other in a manner resembling chemical reactions. But these reactions differ in the laws of combining proportions are not followed. The is true for the coagulations by electrolytes, in which a portion of the electrolyte is taken down, but in no simple portion.

### The Electric Properties of Colloids.

The reactive properties of colloids can be largely explained by the fact that the particles carry an electric charge. This is shown by the fact that when an electric current is passed the particles move either to the cathode or the anode. They may be accordingly classified as positive or negative colloids. Examples are:—

#### POSITIVE, TO CATHODE.

Colloidal metals—

Gold, silver, iridium, palladium, cadmium, selenium, tellurium.

Sulphur.

Silicic and stannic acid.

Tungstic, vanadic.

Metal sulphides.

Halides, etc., of silver and other heavy metals.

Ferrocyanides of copper, zinc, iron.

Aniline blue.

Starch, glycogen, gums.

Congo blue—Congo dyes.

Dianil blue.

Licht blau.

Probably the wandering of "dyes," etc., since "gels" (see later) also retain an electric charge.

#### NEGATIVE, TO ANODE.

Colloidal metals—

Gold, silver, iridium, palladium, cadmium, selenium, tellurium.

Sulphur.

Silicic and stannic acid.

Tungstic, vanadic.

Metal sulphides.

Halides, etc., of silver and other heavy metals.

Ferrocyanides of copper, zinc, iron.

Aniline blue.

Starch, glycogen, gums.

Congo blue—Congo dyes.

Dianil blue.

Licht blau.

### Colour Changes.

An interesting experiment showing the relation of particle size to the state of solution and chemical reactivity is the following.

Phenolphthalein shaken up in alcohol gives a fine emulsion.

On adding acid, the particles immediately agglomerate.

On adding alkali the particles disappear and give a red solution.

Thus, the difference between a true solution and a real is strikingly shown with certain of the new sensitizers—pinacene blue. In alcohol and other organic solvents it gives a solution, which is deep blue, and shows two characteristic absorption bands. In water it is rose red, and has a flat band in the green. But on heating the aqueous solution to 100 deg. it becomes blue, and goes into true solution. This change is reversed on cooling, and the behaviour is similar to starch. It shows how one and the same substance can give all grades of "solution" according to the conditions, or, better, "milieu."

### Milieu.

A very useful term to express the general physical and chemical conditions is the French word "milieu." This implies all conditions as acidity or alkalinity, presence of electrolytes,

etc., temperature, nature of solvent. The reactions of colloids are throughout determined essentially by the milieu.

### Electric Charge and Properties.

I must ask you to return for a moment to a consideration of the electric charge of colloids. We consider also that electrolytes are charged, and we have electric dissociation in solution with positive cations  $\text{Na}^+$  and negative anions  $\text{Cl}^-$ . But whereas in electrolytes the sodium atom is always united with the same quantity of electricity, with colloid particles this is not so—i.e., the ratio of mass to charge is indefinite. So far it appears that the charge is due to a small quantity of absorbed electrolyte, the last trace being almost impossible to remove. I shall have more to say on this point in dealing with the preparation of colloids and their purification. It is this electrified condition which is responsible for most of the reactions of colloids.

### Coagulation by Electrolytes.

Thus the coagulation by electrolytes depends for positive colloids (iron hydroxide, etc.) only on the anion, for negative colloids on the cation. Further, a certain definite amount of the electrolyte is necessary, but it is found that as the valency of the ion increases, so does its coagulating power. Taking the case of arsenic sulphide, and reckoning the coagulating power of potassium iodide as unity, the following values were obtained:—

Potass chloride	.....	KCl 2.5
Sodium sulphate	.....	$\text{Na}_2\text{SO}_4$ 2.5
Calcium chloride	.....	$\text{CaCl}_2$ 80
Magnesium chloride	.....	$\text{MgCl}_2$ 182
Zinc sulphate	.....	$\text{ZnSO}_4$ 60
Aluminium chloride	.....	$\text{Al}_2\text{Cl}_6$ 1518
Aluminium sulphate	.....	$\text{Al}_2(\text{SO}_4)_3$ 957

The solution in consequence becomes acid or alkaline, according as the cation or the anion of the salt is absorbed.

These numbers are inversely proportional to the time required to produce the same degree of coagulation. (A certain quantity of the electrolyte is always taken down.)

### Protective Action of Colloids.

The coagulative action of electrolytes may be hindered by the presence of organic colloids, such as gelatine, albumen, etc. These, added to inorganic colloid solutions, render them more stable. The action is known as "Schutz-wirkung," and is due to the added colloid forming a protective sheath round the particle. This action is illustrated in emulsion making, where the gelatine acts as "Schutz-colloid," preventing both too rapid action of the electrolytes present in "flocking" and also shielding the haloid from "germs" which would give rise to fog.

### Reversible Alterations of Condition. Jellification—Gels.

The process of jellification has long been known. If a solution of sufficient strength of organic colloid is cooled, it jellifies, giving a half-solid gel. On warming, it again goes into solution. As a matter of fact, jellification can, under certain conditions, be obtained with certain inorganic colloids, notably the soaps—but the conditions are more difficult to determine exactly. Hardy was the first to submit the process to an exact investigation. His researches showed that an agar gel consists of a half-solid and more concentrated part or phase, and a fluid, less concentrated (as to agar) phase. This has been confirmed by Quincke, and in such "gels," as well as in the more complicated case of emulsions, we must assume a solid phase and a relatively liquid phase enclosed in cell walls.

The temperature of the passage from the "gel" condition to the "hydrosol" is known as the "melting point," but it is by no means so exactly defined as the melting point of crystalline substances. It has none the less been taken as the quantitative datum in several investigations. Similarly the temperature of jellification is known as the "setting point." Interest-

\*  $\mu$  = 1-1,000 mm.

$\mu$  = 1-100,000 mm.

ing experiments as to the influence of the "milieu" on this have been carried out, and the question is one of considerable importance in photography.

#### Setting Point—Influence of Salts.

Pascheles found for gelatine the following:—

Chlorides, bromides, iodides, and nitrates lower the setting point; with increasing concentration the action is at first slower, then more rapid.

Sulphates, chromates, citrates, and tartrates, further, sodium acetate and glycerine, raise both the melting point and the setting point.

Arranging the salts according to their capacity for favouring or hindering the gelatinisation, we get:—

Sulphate.	Chloride.
Citrate.	Chlorate.
Tartrate.	Nitrate.
Acetate.	Bromide.
(Water).	Iodide.

It is found that the influence of salts is approximately the same in order as for their action on the swelling of gelatine, to which we shall come shortly. An exact explanation has not yet been found.

P. von Schröder concluded that in gelatinisation there were three simultaneous actions.

(1) A hydrolytic or saponifying action of the water, this alteration of condition being irreversible, and marked by a gradual decrease in the viscosity of the solution.

(2) The temperature alteration causes an actual reversible change of condition, the system

Hydrosol  $\longleftrightarrow$  hydrogel.

(equilibrium)

passing with increasing temperature to one, with diminishing temperature to the other, condition.

(3) When the temperature equilibrium has been adjusted, there shows itself, after a long time, thermic changes (Nachwirkungen) resulting in increased viscosity.

Hence gelatine solutions are always changing in properties, and one cannot compare, say, two 5 per cent. solutions of gelatine unless they have both passed through exactly the same experiences since their birth. They must have been boiled off the same bone and had the same life subsequently.

#### Colloidal Condition.

In dealing with solid colloids we enter particularly the region where the history of the substance is of immense importance. In industries where the end substance is a solid colloid, what is desired is what may be termed a "colloidal" condition. An example is vulcanised rubber. The properties depend on the preparation, the temperature of the vulcanisation the rate of cooling, and so forth. Similarly for steels and glasses. Such conditions are never permanent, but show a change with time, and the object in manufacture is to make this "hysteresis" as slow as possible. Photographic emulsions show a similar state of affairs.

#### The "Salting Out" of Albumens.

A process with some analogy to the coagulation of inorganic hydrosols is the "salting out" of albuminoid bodies by con-

centrated salt solutions. But here the change is reversible, coagulum can be redissolved, and the amount of salt required is much higher, only very concentrated solutions being effective. Especially applicable are sodium chloride, magnesium sulphate, ammonium sulphate, and sodium sulphate.

It is found that each albuminoid behaves specifically, order of action of the salts being different. Moreover, excess electrolyte REDISSOLVES the coagulum, so that the action holds between limits. It has been applied to the purification and separation of the different albuminoids.

The ratio of electrolyte to albumen at different temperatures in the precipitate varies, so that the action is not chemical.

#### Mutual Precipitation of Colloids.

Colloids of opposite sign can precipitate each other. The dyes of opposite charge precipitate, but above a certain concentration either is soluble in the other component. This is of importance in sensitising with dyes, in preparing screens, and in all work involving the use of dyes.

Similarly charged colloids do not precipitate, and with similar there is always a zone of coagulation followed by resolution.

10 ccs. gold hydrogel with 1.4 mgm. gold + 5 ccs. colloidal thorium hydroxide of variable concentration.

Mgms. Thorium Oxide.	Phenomena observed.	
	After mixing.	30 minutes later.

3.0	" slowly.	" " "
4.0	Very fine clots. "	Clots completely pptd.
5.0	No ppt.	No change.

#### Jellies, Membranes, and Precipitates.

These are, of course, of quite special importance for photography. And here we are even less able to generalise, for the "colloidal" condition depends at every point on the history and the milieu or environment.

**Membranes.**—As the photographic layer, whether on photographic plate, on paper, on zinc, or on any other surface, is termed a "membrane," the investigation of these is of greatest moment. Membranes are gels which may arise by

(1) Precipitation: When the solutions meet at a surface.

(2) By drying of a colloidal jelly.

The structure of gels has been the subject of investigation by Lehmann, Quincke, Butschli, and others.

Briefly, it is found that gels (jellies) possess a micro-structure, which we may compare to a sponge. But the nature of the property of jellies and solid colloids are too complete to be missed at the end of an introductory lecture, and we shall touch upon specific points as we go along. S. E. SHEPPARD.

The next lecture will deal with the preparation and investigation of colloids, and with certain applications to photographic problems.

#### CONVENTION LYRICS No. 4.—

A knowing young "sitter" of Bruges  
Has a skin of the tint of gamboge;  
Her artist, she states,  
Does not use "Iso" plates,  
So she put on some powder and rouge.

**PLATINOTYPE ENLARGEMENTS.**—Our paragraph of last week in reference to the reduced prices for platinotype paper has been the cause, we are sorry to say, of some inconvenience to several enlarging

firms making a special line of platinotype enlargements. Although as we stated, in certain sizes the reduction of price is to the old figure, this is so only in the cases of small cut sizes, and apparently connected with the wastage in cutting up. In the case of the full size sheets used by enlargers, the reduction, though considerable, does not bring the cost of the paper back to the old price, and enlargers therefore cannot be expected to return to their tariff of four years ago. Fortunately, the public appreciation of platinotypes has also greatly advanced a good deal since this time.

## AN ENGLISH JOURNALIST IN AMERICA.

The following paper by Mr. Thomas Bedding, formerly Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY, and now joint-editor with Mr. John A. Tennant, of the "Photo-Miniature," was read at the London and Provincial Photographic Association on Thursday evening, June 4.—Eds. "B.J."]

first duty, and my greatest pleasure, in writing this paper, wish the London and Provincial Photographic Association all success and long life in its new home. For twenty-six years the L. and P. has symbolised all that was best in practical journalism relating to the process of photography; and the fame of the record has spread to America where it is held in great esteem. The Association also stood for freedom of discussion, and I hope to continue to do so.

### American Society Life.

Now, you may ask, does the photographic world of America come within that of Great Britain. The answer of course cannot be enclosed within the limits of a single paper, but the salient features both can, as it were, be set in parallel. To begin with, life in New York, the one city with which I am so far chiefly acquainted, is not a strong characteristic of photographic endeavour. New York Camera Club and Camera Workers, a recently founded organisation absorbing members from the Photo-Secession, is the nearest approach to the Royal. There appear to be very minor camera clubs scattered about the city; but their influence is possibly smaller in their respective spheres than, let us say, the Hackney Photographic Society, the North Middlesex, the London Camera Club, the South London, in the influence they exert both locally and nationally.

In the whole of the United States there are probably not more than a hundred amateur photographic societies, and these do not differ from anything like the active and strenuous life which characterises English societies. The reason for this is, I think, that photography, like everything else in this wonderful land, has been robbed of all mystery and complication; has been forced down into such a state of simplified efficiency that there is no further need to talk and talk about its difficulties and failures as you and I were to do a few years ago in the City of London.

The American amateur of to-day knows nothing outside simplified photography and its necessary concomitants. He has no use for ingenious complexities which increase weight, complicate procedure and make results difficult to obtain. I will give you a characteristic illustration of the rapidity with which things are done in New York.

### The Fourth Estate.

Early this year a distinguished French editor came to New York and was interviewed by a Press representative before he left the city. The New York reporter and press photographer have the reputation of being the smartest and swiftest in the world. A celebrity or notoriety arriving on the Mauretania in New York Bay have one of the hardest tasks of his life to evade the wily members of the American Fourth Estate. An interview must be made in the paper, even if it has to be invented. But this is a matter of the greatest ease to my resourceful confrères. Our French reporter was complacently and cheerfully told the reporters what he thought about America and its institutions before he landed in the country. Great was his astonishment, when he reached his hotel an hour or so later, to find a copy of an evening paper containing not merely a detailed account of the interview with him, but his own portrait and biography! He subsequently expressed undoubted admiration and surprise at this remarkable instance of journalistic celerity, and deplored the fact that although he had the aid of a large and able staff he could not do things so quickly as this. But rapidity of thought and action are the commonest characteristics of these remarkable people. They have no use for daydreaming and the philanderer. So it goes all round. The daily papers, with few exceptions, are freely illustrated with photographs, and are published lavishly. The Yellow Press has some unkind things to say of it at times—and deserves them—but it is bright, enterprising and sparkling, if occasionally inaccurate. Still, journalistic scruples count for nothing in this delightful place, where dullness and stodginess and suburban priggishness would not be tolerated. I am pleased to say, however, that the New York papers are never

indecorous or prurient, whatever the ignorant may say to the contrary. I should like to give you some idea of the extent to which photography is applied in the New York Sunday papers—such as "The Times," "The World," "The Herald." They are simply vast collections of sheets on which innumerable half-tones covering the whole of the pages and extending in size to the full limit of the sheet are beautifully printed. The public appetite in New York for newspapers appears insatiable, and it really seems as if too many illustrations could not be given to them. But I must switch off this fascinating topic, to which I shall be referring elsewhere at greater length.

### Pictorial Renaissance.

With the dismemberment of the Salon whose epitaph I said I would write fourteen years ago, and the publication of which cannot longer be delayed, the supremacy of the world's pictorial photography passes without challenge to its proper home, New York. The last of the photo-fakers has gone, and not all the genius of Mr. Alfred Maskell can ever bring back the old usurpation. Here in New York are such workers as Alfred Stieglitz, Steichen, Coburn, Clarence White, and many others, all carrying out the ideas enunciated by Dr. P. H. Emerson in "Naturalistic Photography" over twenty years ago. I was rebuked for calling the gum-bichromate process dead. So it is in the eyes of all true pictorialists, as Mr. William Crooke very properly pointed out the other day. It is to be regretted that such a beautifully responsive medium as photography should ever have been handicapped in progress by the gum and similar processes—which have no real place in photographic formulae. It is time that the straight negative and the straight print were restored to their proper place now that the gospel of photo-faking and gum-spodging is dead and buried. I am glad that my recent re-entry into photographic journalism synchronises with the opportunity of showing that I was never at any time an implacable foe of pictorial photography, but only of senseless and debauching photo-faking, photo-falsification, photo-dodging. You know what I mean.

### To the Manufacturer.

Notwithstanding the tariff there is a fine field for British-made photographic goods in the United States. The manufacturer must throw off his conservative prejudices and put himself in a position to supply the requirements of the alertest and most sympathetic people he could possibly do business with. High quality of product must go hand in hand with simplicity. If a printing process, a camera, lens, or other piece of apparatus of European origin does not make its way on the American market be sure of one thing, it fails because it is not simple.

Even after this short residence in America some of the photographic products of the old land look absurdly complicated and cumbersome. There is a master mind at Rochester, N.Y., which has for years been engaged in simplifying photographic apparatus and appliances, and teaching photographic workers how to use them. What think you of a great professional school with a large and perfect plant and organisation travelling through the chief cities of the United States showing professional photographers what to do and how to do it? Of course, it is the demonstration idea carried out on a vast scale, not in the charming perfunctory manner in which you and I see the thing done at the "L. and P." For all that, however, I am sincere and patriotic enough in the belief that the best British photographic productions equal the best of other nations. There is room, and to spare, for a great trade in America, if local conditions are carefully studied and complied with. I could name a dozen good firms who could do an excellent business in the United States if they would only come after it. They should write to me.

### To the Author.

America is the land of incisiveness. Words are no more wasted than is time. These last months I have been passing through a process of simultaneous learning and unlearning. To remodel one's literary style in compliance with the requirements of American

journalism is no easy thing; but I am not without hope that I shall be completely successful at an early date. This leads me to the point where I may usefully tender a piece of advice to the conductors of the British photographic papers (whether they will take it is another matter, and I shall not much care if they do not), the writers in them, and the authors of books—compression, condensation, and the lopping off of all superfluous words would greatly accelerate the popularity of English books and periodicals in America, where they are always welcome. The alert American mind is intensely practical and likes to go straight to the heart and point of a thing without having to force its way through a forest of obstructive words. It is right to say that my work on the publication with which I have the honour to be associated

drives this lesson home to me all the time, but I have also come to the conclusion independently and after months of disquieting reading. The wordiness and diffuseness of many English books are repellent to American eyes, trained from their early growth to rapidity of perception. For my sins and for my duty, yoke these last few months I have been obliged to read and re-read many of my own articles of long ago. They look elegantly journalistic, I suppose, but if I had to write them now I would write them differently. Ah, indeed I would.

It has been a pleasure to me to write this short paper; I should much like to be present at this moment to read it to you. But my astral body is in your midst. So may the good old "L. and Co." flourish!

THOMAS BEDDING

## THE NEWSPAPER FREE PHOTOGRAPH.

[A New York newspaper having set going a scheme which some be interesting to quote an account of the incident from our American surprise to find the New York professional, whom we have been of a newspaper firm by offering to make portraits for nothing in However, as Mr. Abel points out, they have not been slow in

"Do you take coupons here?" has been the cry all over Greater New York during the past week at the studios. There were free photographs to be had for just a mere slip of paper—"a cabinet photograph without charge or obligation," and as the gigantic offer was well advertised by the publishers of the "American," it is not surprising that every street gamine and the biddies and shop assistants, and the Italians of the East and West Sides and all the other *hoi polloi* were quick to take advantage of the offer.

And just how has the photographer fared in the matter?

I have tried to find out, and I think a few of my experiences may be interesting to those who were wise in their generation and resisted the wiles of the "American" agents.

In the first place, it appears that a number of very estimable photographers were persuaded into the free photograph scheme by being told that certain well-known photographers had entered into a contract with the "American" and that they thought the plan an excellent one. I understand that Schloss' name was used frequently in this way, though, of course, Schloss' Broadway Studio was missing from the published list. Many photographers, after having signed, wished to withdraw and were almost threatened into leaving their names on the list. It was shown to those who were picked out for the honour (?) what a wonderful thing it would be for them—that they would get the benefit of the extensive advertising in the "American," and of the re-orders which everyone would naturally give. That these re-orders existed largely in the minds of the agents has been well proven to the photographers, for with few exceptions only the most undesirable class of sitters has presented these coupons. The photographers themselves were quick to see that there was going to be very little money in it for them and devised all sorts of schemes to get round their agreement with the "American." Having agreed to do a certain thing, it was up to these photographers to do it, but I find in many instances that any kind of plausible excuse was given to get out of taking the picture demanded.

Many of the photographers, particularly in New York, made a charge of a quarter or ten cents for retouching. If the coupon-holder would not pay for retouching then he or she was told that the print would not be ready for three or four weeks.

Others asked ten cents for a proof, if a proof was desired.

Others again asked for a quarter if a proof was desired in a day or two. Otherwise it would be some two or three weeks before a proof could be shown.

In New York at least, and probably in Brooklyn too, the first question asked was, "Where do you live?" and if by any chance the coupon-holder did not live within a block or so, he was told that he must go to another photographer. Some photographers on Sixth Avenue, New York, sent the sitters to the next studio, and the photographer there, in turn sent them back again. At one Sixth Avenue studio, if the coupon-holder was well-dressed he was told

papers in this country have used as a bait to their readers, in a contemporary, "Abel's Photographic Weekly." It is somewhat brought to regard as a keen business man, playing into the hands of exchange for some advertisement of very problematical value. Discovering the folly of their assent.—Eds. "B.J."]

that he ought to be ashamed of himself for trying to get a photograph for nothing, and in many other ways the coupon-holders were made to feel cheap.

To those photographers who had refused to enter into the scheme the whole week has been one prolonged misery. The public do not understand that the coupons had to be presented to one of the photographers on the printed list, and only to them. They were shown to their favourite photographers or those whose names were well known. "All day long the doors have swung open and 'Do take coupons here?' has been asked until it became wearisome; every newcomer was suspected of being a free sitter." One photographer on Grand Street, New York, who has had the same scheme for some fifteen years, was overrun on Sunday by some 500 Italians and other East Side dwellers, who could not understand that the coupons were not good at his studio. He probably has incurred the ill-will of many East-siders through no fault of his. One photographer told me he would gladly have paid the coupon-holders to stay away from his studio, if he could have afforded it, but as it would have had to waste his time, his plates, and material with the prospect of getting anything back. One Brooklyn photographer said, "Of course, this is a free photograph, but I shall expect you to buy half a dozen at least, otherwise there would be nothing in it for me."

The fact that nearly all the photographers were anxious to make the sittings, that they sent the holders on to other studios or made any kind of excuses proves that the scheme was thoroughly bad one from the very start, and it will be a lesson to them that they will not easily forget. Thousands of pictures have been made without any hope of extra orders, and thousands of men and women have been to more than one studio with coupons and had two or three or more pictures for nothing. The fact that the sitter was supposed to live in the neighbourhood of the photographer was quickly caught on to, and naturally fictitious addresses were given so as to fool the photographers. Not one photographer I visited personally or by proxy admitted that he was going to money out of it, and nearly all were more than sorry that they allowed themselves to be fooled by the "American."

As I anticipated in these pages, the scheme has been a vast failure as far as the photographers go, but probably the "American" is satisfied with the number of copies sold, and the local dealers at the studios should have done a good business in plates and paper and mounts.

Looking at it another way, this big free picture scheme has many good points. Ticket schemes are and always have been prevalent in this city. From Fifth Avenue to Avenue A, from the Bronx to Battery, photographers are working schemes of one kind or another that cannot be classed as legitimate, legitimate in so far as the public gets exactly what it expects to get. Whether it be an order on some photographer for a portrait for a fictitious book of photography or a ticket entitling bearer on payment of a small sum

ure, promised by the agent to be the very best work of the photographer—a promise seldom or never kept—or whether it be any one hundred other schemes which hold out false inducements, each every one of these schemes lowers the standard of photography business, and tends to make it a fake in the eyes of the public. A small man on the East Side is jeered at for entering the "American" free picture scheme, while the big man, with more money and more help at his disposal, works precisely similar schemes in quiet. The one is as bad as the other in countenancing suchness. In this "American" scheme I believe there are few, very few photographers giving the public just what they are led to

expect. Everywhere there is some little nigger in the woodpile, and so it is with all schemes.

This big free offer, then, may have this good in it, that it will show the public the fake quality of the ticket which for a small sum entitles the holder to a picture the photographer is willing to make for nothing, and it will help to kill that bane of the photographic business, the ticket-solicitor, and further, the public will probably have learned that coupon or no coupon, promises or no promises, the photographer is in the business for the money and is not giving something for nothing, as long as he can figure any way out of it.

J. C. ABEL.

## THE CARAVAN FOR PHOTOGRAPHIC PLEASURE OR BUSINESS.

[From the *Times* of Monday in last week we reprint an article on its attractions for the amateur photographer, and is, moreover, reaching out-of-the-way villages and hamlets. A caravan fitted for amusements in our advertisement pages.—Eds. "B.J."]

For the amateur photographers van life is finding increasing favour, and it is expected, for it enables better photographs to be taken wherever results to be obtained. The ordinary tourist cyclist, motorist, or pedestrian on a rapid journey can, as a rule, photograph one side of a view. He passes a particular spot only once, before the sun is high; and, though by luck he may be there when the light is photographically right, he may be there when the light is wrong. A caravan photographer waits—waiting he is accustomed to or he does not be a caravanner—until the light pleases him, and then he takes his photos or presses. Most landscapes or seascapes yield far better photographs either early in the morning, soon after the sun is up, or in the evening. These two specially favourable periods of the day, as well as all others, are at the disposal of the caravanner, who also has the advantage of a dark-room on the spot for seeing how he or she has not, succeeded in his efforts—for with a little ingenuity the interior of a van can easily be made non-actinic, wherein developments as well as changing plates can be carried on. A well-equipped horse-drawn light travelling van which can be converted with little trouble into a dark-room as well will no doubt before long be put on the market. But in this direction, as in all other directions connected with caravanning, the advancements and improvements come, as up to now they have come, from private and practical enthusiasts and not from the trade.

The carriage-builders in this country have not yet given enough thought to the construction of caravans. The American framework under-carriage are much more suited to touring vans than those found in many of our home-made vehicles. Iron T-pieces and bass wood for panels, or some other material not shrinkable or to crack in sun or rain, would seem to be more suitable for this kind of vehicle than heavy woodwork of mahogany or oak.

### An Hotel on Wheels.

The expert caravanner is he who has acquired the art of packing up his effects in the incredibly small, making the combination of space less than either. He is full of ingenuities for circumventing the difficulties of weight and bulk. He is always fighting the unnecessary; learning the art of discarding. The ideal which all along is his guide is to the convenience of a modern hotel into a parcel to be carried in a pillow-case. The art of doubling is his—"The chest contrived to hold a double debt to pay, A bed by night, a chest of drawers by day." A caravanner imbued with this spirit of concentration can go far and see much country. Of course, such aspirations will not enter into the practical politics of the luxuriantly inclined, who will take to the road to get up an appetite or, maybe, create a desire. One caravanner I know bought a van resplendent with brasses and glittering metal adornments. After a day's arduous journey he cleared the lot out, dumped it down at a wayside village smith's, and sold the gaudy and heavy superfluities for old iron, departing more merrily on his way a wiser and a lighter burman.

### Types of Vans.

The beginner should bear in mind the fundamental principle—the larger the van the nearer to civilisation and the haunts of man.

dealing with the practical side of caravanning, a form of travel which is employed to advantage by professionals able to use it as a means of doing photographic work can often be purchased through the small advertisements.

For touring purposes a one-horse van is much preferable to a two-horse vehicle. In the first place, it is easier to get one good draught animal than two, and experience has shown that the best type of horse for the work is not an omnibus horse or ordinary hackney, but an agricultural horse accustomed to draw the plough. A one-horse van, too, can go into many places where a two-horse cannot. The van can be one or two skinned—there are plenty of advocates for either type. The two skinned van is made of light wood, two-ply, with an air space between so that the internal heat is kept in during cold weather; and the heat is kept out during the hot weather. The one-ply walled van is much lighter, of course, and if arranged with hooks all round the top and bottom of the exterior, for suspending a canvas coat thereto, is nearly as efficacious in heat and cold excluding properties as its two-ply brother.

### Interior Fittings.

The internal arrangements are nearly as diversified as are vans themselves. The consensus of opinion up to the present points to the desirability of the main entrance being in the rear, and there by a door opening inward of two narrow pieces, not running back into the walls. Such a van can be readily entered at any time on the road without stopping progress. Another short door on the near side beside the driver's seat is also desirable, and a small window just behind him, so that free access to the front at all times, even when travelling, is obtainable; for, *pace* the yachtsman, it is always desirable and pleasant in a van to speak to the man at the wheel. Some vans, especially those attached to travelling circuses and theatres, are entered in the middle by a door on either side. On one hand in the interior, across the end, is the fixed bed, on the other the stove, and the centre holds the table. Others are divided by doors, mirror clad, into two separate compartments, with fixed couches all round, convertible into beds at night. Such are all heavy and mostly require two horses to draw, the average day's journey being eight to ten miles. A light, modern van, with 7ft. clear head room inside, which arrived at the recent caravan meet at Ockham, was noticeable for its ample day-room space. A set of lockers on the floor on the off side, with two long light benches placed close to them at night, afforded a good bed, the horsehair mattresses—cushions by day—being placed on top. On the near side a set of lockers near the top ran along the length of the van, with doors hinged to open downwards. These lockers, not being placed close up to the top, afforded there a useful shelf. At night a military camp bedstead was opened out beneath them. The table folded flat against the wall below this set of lockers; and just above it a hinged iron spring mattress could be set out at right angles to the wall at night, when the interior exactly resembled a cabin with three bunks. This particular van had come from Reading in one day, drawn by one horse without fatigue or hurry, a distance of over thirty miles. The ordinary caravanner's day journey is from ten to twenty miles. Needless to say, this light draught van was on high wheels. Vans on small wheels are heavy to draw, and are to be avoided.

There is no reason why a van should not be well lighted up at night so as to ensure ample illumination for reading and writing,

and the system of acetylene lamps would seem to be especially adapted therefor; but up to now no maker has given serious attention to this branch of caravanning. Cooking is done at a fixed enclosed stove in many vans, with a chimney pipe carried through the roof—a system which allows a good drying locker for clothes to be built around the pipe at its upper end. But light touring summer vans save this great addition to the weight, and use simply paraffin wickless lamps, burning a mixture of air and ordinary oil on the Bunsen burner principle. Such lamps give intense heat and no smoke. Many vans carry light portable tents for putting up friends at night, and for bathing purposes, all sorts of portable baths and basins of canvas being carried for that purpose. Aluminium vessels are now largely used, and folding furniture of even a luxurious description.

#### Prices of Vans.

The price of a van varies within very wide limits. A motor van which visited the recent caravan meet at Ockham was driven by a 48-horse power engine, and lit with electricity from accumulators, and

cost hundreds. Another one-horse light touring van (which was also at the meet) was built by its owner for £40. A van was travelling in England last year which cost at least £2,000. Between the figures the intending caravannist has ample choice, to suit his own idiosyncracies and pocket. The demand for vans is now in excess of the supply—that is, for modern light touring vans—and consequently many old-fashioned and heavily equipped vehicles are being unearthed and furnished up, which will cause more trouble than they are worth. Gipsy vans are also being brought forward. They should be viewed with grave suspicion, and if one be purchased it should be well disinfected. Seldom, if ever, is a gipsy van worth what is asked for it. A good watch dog—a “demon guard,” as it is called—is most valuable while on the road; one that can be left in charge of the vehicle during temporary absence. But perhaps the most essential point of all to remember in fitting up a van is to have a really comfortable bed. Unless a good night's rest be always obtainable, the benefit of caravan life will be much lessened.

## MAGNETITE ARC LAMPS.

[Arc lamp usage is undergoing transitions which are almost as startling and as far-reaching as the upheavals which are at present disclosing themselves in the incandescent lamp field, and a very interesting contribution to the literature of the modern arc lamp is found in the “Electrical World,” of New York, contributed by Mr. G. M. Dyott, who reports the results of some investigations made by him in the use of metallic arcs in which the usual carbons are replaced by metallic electrodes.—Eps. “B.J.”]

THE value of the light for photo-mechanical purposes has not as yet been fully determined, but from the character and control of the rays emitted, there should be found interesting possibilities in the specific application of the new method to process uses. It is stated that the total light emitted by a 300-watt arc is approximately twice as great as that from an alternating-current series enclosed carbon lamp consuming 450 watts. The life of the electrodes also compares very favourably with that of the latter, two hundred hours or more being allowed between trimmings. There is a radical difference, however, between the magnetite arc and the ordinary carbon arc in practically every respect. The magnetite arc can only be maintained on a direct circuit, and should be used in conjunction with metallic positive. If the magnetite electrode is used for the positive as well as the negative electrode the arc loses some of its brilliancy, and in consequence its efficiency is impaired. It is found that the positive electrode, when metallic, lasts two thousand hours or more, but when this electrode is composed of magnetite it is consumed fairly rapidly. On alternating-current circuits it is impossible to maintain an arc unless specially prepared electrodes are used. The magnetite electrode must in all cases form the negative, and, as a rule, has been placed in the lower holder of the lamp. On account of the character of the arc, which is dependent on its composition, it is the most important of the two electrodes, and the size of the positive has little effect on the behaviour of the arc; ordinarily it is found satisfactory to make it of a heavy copper rod one inch in diameter. The negative electrode for experimental purposes can be made from the following materials:—Magnetite iron ore,  $\text{Fe}_3\text{O}_4$ ; chrome iron ore,  $\text{FeCr}_2\text{O}_4$ ; titanium oxide,  $\text{TiO}_2$ ; but for commercial work it is necessary to add other substances, which serve to steady the arc, and in regular use the bulk of the electrodes consist of magnetite iron. At this point we begin to be able to see the possible value of the specific quality of the rays for photo process purposes, as it is found that an arc maintained between electrodes of pure magnetite is very rich in blue and ultra-violet rays, but unfortunately the arc is very unstable and emits fumes very copiously. The arc issues from the negative at a point and spreads out like a fan towards the positive. Excessive blue rays emitted by the iron arc alone are largely neutralised with a consequent increase of ordinary luminous efficiency by the addition of titanium oxide in varying proportions according to the other materials used. An arc produced between electrodes of this oxide alone is very brilliant, being of a pure white colour giving off fumes, and forming an insulating slag when cold. It, however, is also very unstable, and the area of luminosity is very much reduced. When the oxides of magnetite and titanium only are used the instability of the arc becomes so great as to render it unsuitable for practical purposes.

In order to overcome these defects, and at the same time increase the life of the electrodes, either oxide of chromium or chrome iron ore,

called chromite, is added, the latter being thought the better of the two. An arc formed of the oxide of chromium is of a dull greenish-yellow colour, and burns steadily, its luminous efficiency being low. The consumption is very slow, and scarcely any fumes are given off, but it forms an insulating slag when cold. The shape of the arc is different to that produced by the previously mentioned compositions, being of about the same width throughout its length. The distinctive characteristics of these metallic arcs is found in the fact that the area of greatest luminosity occurs adjacent the negative electrode, which is the reverse of that found in ordinary practice with carbon electrodes, wherein the area of greatest illumination is found on the positive carbon. The obvious solution for the greater operational efficiency would be the placing of the magnetite in the position of upper carbon, and the copper electrode in the position of the usual lower electrode, sending the current from the copper to the magnetite; but there has been a great deal of difficulty encountered in effecting this arrangement, because of the difficulty in holding the magnetite electrode in mechanical cohesion, but recently there has been placed on the market a lamp which brings about this result. The voltage drop in a one-inch magnetite arc when consuming five amperes is one hundred volts is ninety-three volts, seven volts additional being consumed in the negative electrode between its outer surface and the point from which the arc proceeds.

If the direction of the current is reversed the whole character of the arc is changed. It loses all of its striking brilliancy, and becomes a flaming arc, in the true sense of the word, having a dull yellow colour. The striking characteristics of the arc depend on the negative or magnetite electrode, and it is around the positive or copper electrode that most of the difficulties are found. Among these may be mentioned: First, after continuous service fumes are deposited on the positive electrode, which in adhering to it hang down from the sides so as to completely curtain off the light. Second, material used for the positive, due to oxidation on account of the great heat of the arc, are liable to form oxides, which are insulators when they thereby making it impossible to re-start the arc. Third, globules of molten matter may be taken up by the positive from the negative, such globules affecting the steady burning of the arc. As far as the results of experiments show, the choice of material for the positive seems to be limited to copper, iron, alloys or mechanical combinations of these metals. Iron is consumed too rapidly. Brass appears to be very satisfactory, always being clean, presenting a smooth surface and any globules that may adhere to it at its lower extremity crack off when the light is extinguished. The benefit of these searches made by Mr. Dyott, it would seem, will undoubtedly be taken advantage of by wide-awake process work experimenters. This is especially true in the direction of colour work, and it is thought that the hints given by Mr. Dyott will be of great value in this direction.

## HOLLINGER ON THE SHOW CASE.

W. H. HOLLINGER, the well-known New York professional photographer, at a recent convention of the Professional Photographers' Society of New York, had some striking testimony to make as to the business value of a showcase which is actively used. He said originally he and each of his staff took the showcase for a week at a time, each striving to outdo the other in the display. There were four of them, they each had a month to get ready. It was lots of fun, but very expensive. Now he had the showcase changed every day. He had several ready-made, ready to slip into the showcases. Making a specialty copies, he had one board covered with copies, and this he slipped into the case every second day. In between days he used a board covered with groups, or one showing men's portraits only, or one of children. If he were to keep the copies in for several days together, people would get it into their heads that he made nothing but copies. Therefore he changed every day. Mr. Hollinger said he watched every case on the avenue, and knew which were changed and which were not. And those that were not did "draw" as well as the others. When no one stopped to look at his case he said he would send some one down to look at it, and thus draw a crowd. Mr. Hollinger said his method would at least keep the case clean, which could not be said of all cases.

## LECTURES ON PHOTOGRAPHY AT THE ROYAL INSTITUTION.

DR. SCOTT delivered the third and last of his lectures on Thursday, June 4, beginning it with a demonstration of the printing development of bromide paper. This led to the consideration of the nature of the latent image, and the lecturer favoured a chemical rather than a physical explanation. He considered that evidence pointed to a latent image consisting of silver—that is, the action of light breaks up silver bromide into silver and bromine. Some examples of reversal were shown upon the screen, the lecturer attempted no explanation: he considered the phenomenon to be quite obscure, and did not think that any theory put forward would meet the case at all. The processes of cyanotype, platinotype, and carbon were then dealt with, and applications of the principles of the carbon process in photographic work were pointed out. Colour processes came next, results by the Lippman, Sanger-Shepherd, and Lumière processes were shown upon the lantern screen. Sensitising a bromide emulsion to colour was described as due to the formation of a lake of silver bromide and a dye, and the formation of a lake of alumina carmine was demonstrated. Dr. Scott then referred to the production of photographs by agencies other than light, and a description of Dr. Russell's experiments proving that the effect is due to emanation, probably of hydrogen peroxide, and not to radiation. He drew attention to some interesting tests for the purity of ether of mercury founded on the radio-activity of the peroxide rendered impure by the impure substances. He stated that only about one part in a thousand was pure enough to stand the test, and in the case of mercury an admixture of 1,300th per cent. of ether or 1 part in 30,000, could be detected by this means. Quite pure mercury has no effect, but if a piece of zinc is simply dipped into the mercury and withdrawn again as quickly as possible, the mercury becomes sufficiently impure to affect a plate. Examples of the effects of wood and coal upon plates concluded the lecture.

LATE MR. ROBERT STEWART.—Mr. Robert Stewart, photographer, Elgin, died in Edinburgh on Tuesday of last week after a long illness. Mr. Stewart succeeded to the business of his father twenty years ago. As a photographer his work was widely appreciated. A series of postcard photographs of Elgin "characteristics" of last generation met with a very large sale, and he was well known for his admirable scenic photography, while his early work was of the highest class. Mr. Stewart was retiring in position, his one aim being to keep abreast of the rapid progress being made in his profession, and he took no part in public affairs. At the time of his death he was fifty-eight years of age. He left a widow and a young son.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between May 25 and 30:—

**CINEMATOGRAPHS.**—No. 11,333. Improvements in synchronously operated cinematograph and talking machines. Heinrich Bayer, 6, Lord Street, Liverpool.

**PLATES.**—No. 11,341. Improvements in photographic dry plates. Bernard Klatte, Chancery Lane Station Chambers, London.

**CINEMATOGRAPHS.**—No. 11,395. Apparatus for protecting cinematographic bands or films against conflagration. Amedée Lertourné, Birkbeck Bank Chambers, Holborn, London.

**PHOTO-TELEGRAPHY.**—No. 11,446. Method of and means for transmitting pictures and the like from a distance. Francesco De Bernochi, 7, Southampton Buildings, London.

**CINEMATOGRAPHS.**—No. 11,551. Improved driving mechanism particularly adapted for cinematograph apparatus. Carlo Rossi, 111, Hatton Garden, London.

**BALLOON PHOTOGRAPHY.**—No. 11,651. Improvements in and connected with photographic apparatus for taking moving pictures from balloons and the like. Thomas Macready Down and Herbert Lindo Mocatta, 82, Mark Lane, London.

**SHUTTERS.**—No. 11,687. Improvements in or relating to photographic shutters. Kodak Ltd., Chancery Lane Station Chambers, London.

**COLOUR SCREENS.**—No. 11,698. Improvements in or relating to the manufacture of screens or coloured surfaces for coloured photography. Louis Dufay, 111, Hatton Garden, London.

**TRIMMING MACHINES.**—No. 11,708. Improvements in apparatus for cutting or trimming photographic and drawing papers and other thin materials or substances. John Merrett, 36, Chancery Lane, London.

**TRIMMING MACHINES.**—No. 11,709. Improvements in apparatus for cutting or trimming photographic and drawing papers and other thin materials or substances. John Merrett, 36, Chancery Lane, London.

**CAMERAS.**—No. 11,746. Improved device for the adjustment of photographic camera fronts and backs. John Arthur Harrison, 28, Chippendale Street, Castle Boulevard, Nottingham.

**ENVELOPES.**—No. 11,779. Improvements in light-proof envelopes for use in photography. Edgar William Houghton and Houghtons Ltd., 88, High Holborn, London.

**CINEMATOGRAPHS.**—No. 11,791. Improvements in and relating to cinematograph apparatus. William Friese-Greene, 70, Chancery Lane, London.

**MOUNTING.**—No. 11,798. Improved method of mounting and preserving photographs, engravings, prints, designs, paintings, and the like. Saul Freedman, 31, Bedford Street, Strand, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**SCREEN PLATE COLOUR FILTERS.**—No. 20,384, 1907. The invention relates to plates or films for colour photography. It is well known that in the manufacture of plates having multiple line or dot screen filters it is almost impossible to prevent the lines or dots from more or less overlapping, owing to the extreme difficulty of obtaining accurate registration. The object of the invention is to provide means whereby the necessity for obtaining registration is avoided. We first print upon the plate or film by any suitable process, as for instance, the fish glue process, a series of lines covering one-third of the area of the plate, for instance, in practice, first a series of straight red lines with intervening spaces of twice the width of the lines is printed, and a sensitive film applied over the lined side of the plate.

Next, a series of, say, green lines is printed crossing the red lines at a suitable angle, using a negative in which the black and white lines are of equal width; instead, however, of placing the negative on or in contact with the coated side of the plate, we print through the glass or film so that the lines first printed form a

portion of the negative, the result being that although the proportions of black to white in the negative used are equal, the printed area owing to the interposition of the previously printed line is only one-third of the total area of the plate.

After development the plate is recoated and exposed to light through the glass, the red and green lines previously applied acting as the negative to cover two-thirds of the area, the remaining one-third being coloured blue.

In printing, the colouring matter may be incorporated in the fish glue solution or the solution may be clear and the prints subsequently stained; in the latter case an insulating film of celluloid or other suitable varnish may be used.

The claims are for:—1. The method of producing multiple line or dot screen filters upon plates or films for photographic purposes consisting in printing upon the plate a series of evenly distributed lines, say red, covering one-third of the surface, then sensitising the surface so printed and exposing the same to light through a negative applied to the unsensitised side of the plate and having a series of alternating lines and spaces of equal width, then staining the sensitised surface so as to obtain a series of, say, green lines crossing the red lines, and finally, after again sensitising the printed side of the plate, exposing it to light through the glass so as to colour the remaining surface blue. 2. Plates or films having a parti-coloured surface produced in the manner hereinbefore described. Edward Sanger-Shepherd, 68, Adelaide Road, Hampstead, London.

**EMBOSSED PHOTOGRAPHS.**—No. 4,523, 1908. The invention consists in a process of embossing photographs or other pictures, consisting in providing a mould having recessed parts in its face corresponding to those parts of the picture which are to be in relief, mounting such a mould on the moving head of a press, placing a layer of a composition upon the opposed bed of the press (this composition being plastic but calculated to set hard) such as a mixture of plaster of Paris, dextrine and water, covering this composition with a layer of paper, bringing down the mould with pressure on to the paper-covered composition whereby the composition and its paper cover is formed to correspond with the mould, then allowing the die to set hard, backing the picture with stout soft paper, which is caused to adhere by means of adhesive. The picture thus mounted is placed upon the composition die with its picture face towards the mould so as to register with the die. It is pressed between the die and the mould, and finally removed and set to dry.

The die is made directly upon the stationary bed or platen of the press with the aid of the mould already mounted on the moving head. By so doing (that is by making the die *in situ* in the press) the die automatically registers with the mould. To carry this out a piece of soft paper, such as thick blotting-paper, is secured by some adhesive material, such as dextrine, to the surface of the stationary platen of the press beneath the wood mould, and the moving head is then brought down so that an impression of the block is produced upon the paper on the platen.

A composition is then prepared consisting of plaster of Paris, dextrine, and water, mixed in such proportions that the paste will not easily flow, and this composition is spread over the paper on the platen or bed of the press, being roughly placed so that there is a thicker layer over those parts marked on the paper pad which will constitute the relief portions of the picture which is to be produced.

Over this composition is then laid a piece of fairly stiff paper, which is firstly treated with dextrine solution on its surface, and the treated surface is then applied to the composition. The paper may be, for instance, glazed brown paper.

The moving head of the press is then brought down carrying the wood matrix, and the paper cover of the die which is to be formed, and the layer of composition beneath the paper, is forced by pressure so that the paper cover enters the intaglio portions of the mould.

The composition and the paper cover may completely fill those intaglio parts of the block where they are not very deep, but in many cases when the mould is brought up again, it will be seen that the soft paper-covered composition has not completely filled the intaglio portions of the mould. That is to say, by observing the impression of the mould upon the paper covered composition it will be at once observed whether the impression upon the material

which is to compose the die is perfect or not, and if it is perfect—which may frequently occur—the paper cover of the composition is pulled off, and this can be done without in any degree disturbing the composition beneath it; and then a further supply of composition is placed upon those portions which obviously require a greater height. The paper, or another of paper treated with dextrine, is laid over the composition augmented, and the head of the press is again brought down. It will be found in most cases that a perfect impression is produced of all the intaglio portions of the mould upon the paper-covered composition which when dry forms the die proper.

A paper copy or print of the original picture is then taken, upon the back thereof is fixed a piece of thick soft paper, such as stout blotting-paper, by a layer of adhesive material, such as dextrine.

The original picture, thus backed, is then placed upon the press with its outlines corresponding to that die—which is effected with the aid of the register marks in the well-known way—and then the head of the press is brought down with considerable pressure, and after remaining under that pressure for a few seconds, the picture can be removed and it will be found that the predetermined picture has been permanently raised and given the effect of a bas-relief. The picture, and the backing of the picture (as the adhesive material holding it to the picture dries) permanently retains the partial relief and prevents the same being again flattened. Allowing Scopes, Dalton House, Dalton Park, Ipswich, and Allington Limited, 115, Newgate Street, London.

The following complete specification, etc., is open to public inspection before acceptance under the Patents Act, 1901:—

**CINEMATOPHONES.**—No. 11,395, 1908. Apparatus for protecting cinematographic bands or films against conflagration. Letourneau

## New Trade Names.

**PELICAN.**—No. 302,333. Chemical substances used in manufacturing photography, or philosophical research, and anti-corrosives, not including sulphate of magnesia, sulphate of lime, aluminium chloride of zinc, and not including any goods of a like kind to those excluded goods. Fritz Beindorff, trading as G. Wagner, 80, Milton Street, London, E.C., ink and colour materials. April 15, 1908.

## New Materials, &c.

**"Satin-Surface" Zigo Self-Toning Paper.** Made by Thomas Illingworth and Co., Ltd., Willesden Junction, London, N.W.

This new variety of the well-known "Zigo" paper should be received with approval. Its surface has the fine matt texture kind commonly described as "carbon." The sample sent to which we have found to tone in the hypo bath in the customary "Zigo" manner—is of a faint mauve tint which contrasts in striking manner with the rich brown of the print. A cream-toned paper would, we think, lend itself to the tone given by the "Zigo" emulsion when prints of a more harmonious character are aimed at. Messrs. Illingworth, who already issue such cream paper in a series of their manufactures, might consider the advisability of applying it also to "Zigo." Meanwhile we can advise applicants to them for a specimen print on the new paper, which is sold at the prices of the other brands of "Zigo."

**BRUSHES FOR THE OIL PROCESS.**—Messrs. John J. Griffin Sons, Ltd., of Kingsway, W.C., have sent us samples of two brushes which they are now supplying for the oil and brush processes. The "Prima" is a fine hog-hair brush mounted on handle and ferrule of convenient shape. This brush is issued in three sizes:—No. 2, 1s. 3d.; No. 6, 1s. 9d.; and No. 10, 3s. 6d. The other is a fitch-hair brush issued as the "Gradator." It is with a metal tube or sleeve which protects the hairs when the brush is not in use, and also permits of the worker obtaining more or less softness in the hairs by pulling out the "sleeve" to greater or less distance. The sizes and prices of the "Gradator" are:—No. 2, 1s. 6d.; No. 6, 2s. 6d.; and No. 10, 5s. Particulars

se and other materials for the new pigmenting processes are available from Messrs. Griffin.

**LEOPOLD PLATONA PAPER.**—Messrs. Ilford, Ltd., announce a reduction of price in their platinum paper, which in future is sold at per tin of two sheets, 24½ x 17, or 1s. 3d. per tin of twenty quarter-plate pieces.

**TRADE PRINTING.**—A price list of trade printing and enlarging reaches us from Mr. B. Matthews, 104, Idle Road, Bradford. The list gives the prices for bromide postcards, black and sepia, carbon arguments, and bromide enlargements finished in black and white. Mr. Matthews, if we may judge from some sheets of postcards which he has sent us, turns out good work at a moderate price.

### CATALOGUES AND TRADE NOTICES.

**MESSRS. BOOTS,** of 29, Farringdon Road, London, E.C., in issue the 1908 edition of their annual catalogue, have introduced a new feature in the form of a literary section. This includes, amongst a quantity of other useful information, notes and hints on the use of short-focus lenses, enlarging on bromide papers, instructions for working "Carbograph," hints on the use of various makes of papers, on mounting, on passe-partout framing and mounting, several useful tables. The section devoted to the description of prices of photographic apparatus, materials, accessories, etc., is well illustrated and comprehensive, and the whole forms a useful guide for the amateur worker, both for choice of apparatus, and useful hints as to its use.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JUNE 13.

**LEWIS PHOTOGRAPHIC SOCIETY.** Excursion to Welford.  
**NEWCASTLE PHOTOGRAPHIC SOCIETY.** Excursion to Bookham.  
**SEA AND DISTRICT PHOTOGRAPHIC SOCIETY.** Excursion to Hayes Common and Keston.  
**WIMBORNE PHOTOGRAPHIC SOCIETY.** Excursion to Charwelton and Badby. W. F. Dawson.  
**A SUBURBAN PHOTOGRAPHIC SOCIETY.** Excursion to Otford and Shoreham. P. T. Edwards.

MONDAY, JUNE 15.

**HAMPTON CAMERA CLUB.** "'Tabloid' Photography." S. G. Kimber.

TUESDAY, JUNE 16.

**LEWIS PHOTOGRAPHIC SOCIETY.** Opening of a One-man Exhibition, by W. Bennington.  
**CHESTER AMATEUR PHOTOGRAPHIC ASSOCIATION.** "Oil Printing" Demonstrated. Rev. H. W. Dick, S. L. Coulthurst, and J. J. Phelps.

WEDNESDAY, JUNE 17.

**SEA CAMERA CLUB.** "Figure Studies." A. Cohen.  
**MIDDLESEX PHOTOGRAPHIC SOCIETY.** "Oil Printing." H. Stuart.

THURSDAY, JUNE 18.

**SEA AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.** "Why and How it was Done." Ernest Human.  
**SEA SOCIETY.** Short Papers.  
**LEWIS PHOTOGRAPHIC SOCIETY.** "The Law of Photographic Copyright." S. S. Taylor.

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—At the meeting held on May 27 a paper on "Some Points in the Design of the Photographic Objective" was read by H. C. Patey and V. H. Kinney.

The authors attempted to give a simple explanation of the causes of the six-lens aberrations and of the means which are adopted to get rid of them in photographic lenses. The function of a photographic lens is to give over a fair sized angular field of view sharp definition over a flat surface, and as a lens system it may be regarded as lying between the systems of the telescope and the microscope, which gives images respectively by means of very narrow or very wide incident pencils. The conditions of perfect, or collinear, relations between object and image were then discussed, and the uses and limitations of the pinhole mentioned.

An example of work done with a pinhole was submitted, and the following formula given (allowing for the effects of diffraction) for the best working distance D of plate from pinhole:—

$$D = \frac{P^2}{0.00064}$$

where P is the diameter of the pinhole in inches. Against the advan-

tages the pinhole possesses of freedom from distortion and flatness of field must be set that of slowness, a slowness which becomes impracticable for portrait subjects, and also want of definition. To get greater rapidity it becomes necessary to utilise a lens which, while receiving a larger cone of light, introduces special defects of its own, which defects or aberrations were next considered.

### THE SIX ABERRATIONS.

**AXIAL.**—(1) Chromatic. (2) Spherical.  
**OBLIQUE.**—(3) Coma. (4) Astigmatism. (5) Curvature of field. (6) Distortion.

Chromatic aberration, due to the dispersive effect of glass on white light, is corrected by combining a positive crown lens of comparatively low dispersion with a weaker negative flint lens of higher dispersion.

Light incident to a spherical surface of glass is not brought to a single point focus, the defect being known as spherical aberration. The correction depends, not on the power (or focal length) of the two lenses in a combination (as does achromatisation), but on the relative disposition of their curvatures. A point lying on the principal axis of a lens is correctly defined by a lens system corrected for these two aberrations, but points removed therefrom render necessary the consideration of the oblique aberrations of coma, astigmatism, curvature of field, and distortion.

Coma is an asymmetrical spherical aberration, the effect of which on the image was shown by means of a slide of a photographed disc, perforated with small holes. It is corrected in lens systems by means of the doublet arrangement.

Astigmatism, the cause of which is the different effective powers of a lens on the various meridians of an incident oblique beam, while the result is two focal lines in the image of a point object, was explained by means of a model of silk threads.

Between the two focal lines due to astigmatism are the circles of least confusion, the nearest approach to a sharp image, and the figure containing these circles of least confusion is the curvature of the field of the lens.

The condition that a combination of the two lenses should have a flat field makes it necessary that the positive crown lens, while having a lower dispersion, should have a higher index of refraction than the associated flint, and this condition, while impossible with the old crown and flint glasses, can be approximately fulfilled by using certain modern Jena glasses. Distortion is caused by a lens or system of lenses having spherical aberration in respect to the stop and the image which the lens may be said to form of the stop, and is approximately corrected in any doublet system.

In conclusion a rough sketch of the means adopted to get rid of the above aberrations in a modern anastigmat lens was given, starting from the basis of two similar single lenses, symmetrically placed about a stop.

## Commercial & Legal Intelligence.

**A NORWICH BANKRUPTCY.**—A meeting of the creditors of Alfred Ernest Priest, photographer, of 21A, Prince of Wales Road, Norwich, and residing at 51, Sprowston Road, was held at the office of the Norwich Official Receiver on Saturday. The debtor's statement of affairs showed gross liabilities £407 7s. 2d. and a deficiency of £359 8s. 9d. Debtor, who filed his own petition in consequence of several judgments having been obtained against him, attributed his failure to "competition in the photographic trade, and losses in my ventures as a lanternist and entertainer." He commenced trading at 129, Magdalen Street, Norwich, in July, 1904, having previously been a watchmaker's assistant. He had no capital, but was in debt to the extent of £70. During the whole of his trading, and before, debtor had undertaken the responsibility of arranging animated picture and variety entertainments throughout the district, and the greater part of his liabilities had arisen in connection with these ventures. Early in 1907 debtor took over a photographic business at 21A, Prince of Wales Road, Norwich, paying in cash and goods about £80 for the apparatus, unexpired lease, and goodwill, and the Magdalen Street premises were given up a few months later. The debtor has kept no books beyond diaries, but he admits having been aware of his insolvent position during the whole of his trading.

Recently, when pressed for cash, debtor is alleged to have sold the more valuable part of his goods and appliances, some of which had not been paid for. Part of the furniture is claimed by the debtor's wife, as having been purchased with her savings. The estate remains in the hands of the Official Receiver as trustee.

## Correspondence.

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### STUDIO DECORATION.

To the Editors.

Gentlemen,—I have been following with interest the article running through the "B.J.P." on studio decoration and construction,

as for the last several weeks I have myself been altering an old matchboard-lined studio—through the shrunken grooves of which dust blew with the least wind—into a presentable and useful studio. I now enclose you two photographs, taken each end, showing the

same studio finished in imitation oak by Messrs. F. E. Jones, of Gray's Inn Road, which has a most realistic effect and the advantage of dust-proof ceiling. In No. 2, the left-hand corner is the changing-room, but by carrying a beam right across the studio it not only kept the

cornice line continuous and pleasing, but made a good support curtains and a darkened recess for a heavy-toned background. Of the great points in its favour is the cheapness, when the effect is considered from both a decorator's and photographer's point of view, as one can practically photograph all round the studio with various effects.—I remain yours truly,

GORDON CHASE (late of Tunbridge Wells)  
1, Princes Avenue, Muswell Hill, N.

### THE PHOTOGRAPHIC CONVENTION.

To the Editors.

Gentlemen,—I shall be glad if you will allow me, through the medium of your columns, to ask those members who have not already advised me of their intention to attend the Brussels Convention kindly to let me hear from them without further delay.

I am anxious to do all I can for their comfort and convenience, but certain arrangements have to be made on the Continent, which cannot be hurried, and it will greatly facilitate matters if I know well in advance, how many are likely to be going, and by what route they intend to travel.

I may mention, perhaps, that the meeting promises to be unusually large, indeed we have already nearly 60 absolutely new members on this side of the Channel alone.—Thanking you in anticipation, remain, Gentlemen, yours truly.

F. A. BRIDGE, Hon. Sec. and Treas.  
East Lodge, Dalston Lane, London, N.E.

## News and Notes.

HER ROYAL HIGHNESS THE PRINCESS OF WALES on June 10th honoured Mr. Langfier, Court photographer, 23A, Old Bond Street, W., with a special sitting.

"PAR EXEMPLE."—

An English girl living in Gand  
Was asked to oblige with a song;  
When asked what she'd sing,  
She said: "God Save the King."  
The Convention is coming; "c'est bon."

SCOTTISH FEDERATION EXCURSION.—On Saturday last the annual excursion of the Scottish Photographic Federation was held at Stirling. The excursionists were met by Messrs. P. D. I. (Secretary), R. K. Holmes, and J. J. Munro, the Excursion Committee, and enjoyed a walk to the Castle via the Back Walk. The sunlight filtering through the trees on the walk tempted not a few exposures. At the Castle permission had been granted to photograph by Major Mackenzie, M.V.O., and the party had the benefit of Mr. Shearer, well known as the publisher of the popular guide to Stirling. He pointed out the salient features of the ancient fortress, and was most helpful to inquiring ones. Mar's Work, Guildhall, and some of the closes around the Castle formed favourable subjects for the camera, and in due time the Golden Lion furnished food for the body. Major Mackenzie presided, and welcomed the visitors in a few felicitous words. Mr. A. Symon, M.A., B.Sc., President, spoke the thanks of those present to the Major, and Mr. Drinkwater performed a like duty to the Excursion Committee. Messrs. Holmes and Nairn acknowledging. A drive formed the afternoon programme. On past old Stirling Brig, skirting the foot of Abbey Craig to Airthrey Castle, open by kind permission of Mr. Graham. Here the reflections of the Wallace Monument in Loch, and a herd of Highland cattle kept the photographers cool, and it was with difficulty that a start could be again made. An endeavour was made to get a "group" (Mr. Dan Dunlop being the camera), but so anxious was everybody to secure masterpieces that a full muster was impossible. Cambuskenneth Abbey claimed attention, and while the architecturally inclined photographed the relics of the past, the "arty" folks stalked with patience and varying success a herd of surprised cattle. A cup of tea in the Golden Lion Hotel made a pleasant ending to a pleasant day, and so the fifth excursion became a thing of the

## Answers to Correspondents.

Matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business matters should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1d. each photograph, to cover cost of registration fee, form, etc. Unmounted copies of each photograph must be sent with the

### GRAPHS REGISTERED:—

Thomas, Show Van, Lowcock's Yard, Great Clowes Street, Salford, Lancashire. Photograph *Lady with Long Hair*.  
 Edie, 416, Union Street, Aberdeen. Photograph of *Marischal College, Aberdeen University*.

—1. Rogers and Webster, High Holborn, London, W.C. do not know the method. The results are very similar to

—2. The firm has no house here. Mr. Baker, we believe, is in Australia. Your best course is to write to Melbourne.

—3. I should be much obliged if you could advise me on this question. I am selling a lot of photographic cards, taken by me. I do not copyright them. Now I find a large postcard dealer making penny ones from same. Please say the best way to their sale, if possible.—R. C.

—4. You need do is to register your copyright in the photographic. This will enable you to stop further sales, but not to prevent penalties in respect of sales before registration. If you wish your publishers can effect the registration. See notice at the bottom of this column.

—5. COMES.—1. I have been getting a brown stain on my Autochromes, and have traced it to the permanganate (c) bath, which I have made up some time. The remedy, I suppose, is to make a weak solution of oxalic acid. If so, what strength? Will Autochromes stand this? 2. Would you kindly give Messrs. Lumière and Leitz's formulæ on page 45 "B.J." Colour Supplement, June 5, 1907, in solid and fluid ounces? Also reduce ammonia .920 to the strength .880.—H. F.

—6. Oxalic acid is the best remover of the permanganate stain. 2. Formulæ are:—

Water .....	3½ oz.
Bisulphite or soda liquor .....	2 drops.
Pyrogalllic acid .....	46 grs.
Potass bromide .....	46 grs.
Water .....	2½ oz. 116 minims.
Soda sulphite anhydrous.....	154 grs.
Ammonia .880 .....	½ oz. 32 minims.

Use, dilute BB to quarter strength—i.e., 1 oz. with 3 ozs. water. For a half-plate take water, 4 ozs.; A.A., ½ oz.; B.B. (or strength), ½ oz.; and use at 60 deg. Fahr. Place at hand for use 2½ ozs. of solution B.B. (quarter strength).

—7. None.

—8. HAPLIN and others.—In our next.

—9. 1. If the negative is sold with assignment, in writing, copyright, the latter is destroyed. 2. The copyrights having been null and void, you (or any one else) can copy a portrait and retain copyright in your copy. 3. We believe not. It is a point.

—10. 1. Yes, certainly. You yourself can publish or through a house. You had better get prices of cards, say from Hood & Co., St. Bride Works, Middlesbrough, or the London Studio, 10, St. Bride Street, London, E.C. 2. Yes, certainly.

—11. GELATINE.—In the course of some experimental work I have done I require to stick down a small piece of thin hardened paper on to a piece of polished metal so as to be transparent

and show the metal through. I have unsuccessfully tried several ways as follows:—Copal varnish would not dry under film; coating of bichromated gelatine solution (substratum) peeled off when dry; fish-glue, smeared on with a drop of bichromate solution, would not become sufficiently insoluble, but came off in water. (It was exposed to sunlight when dry.) 1. I think something like Canada balsam might do it, but I don't know how to use it, and should be glad of advice on the matter. 2. A formula for sticking paper to metal is given in "B.J. Almanac" (gum and aluminium sulphate solution); would this be suitable for my purpose, and what is the purpose of the aluminium sulphate?—FILMO.

1. What you desire to do is not a very easy thing, if the metal is highly polished. The method of using Canada balsam is given, in reply to a correspondent (W. Creasey), on page 428 of the JOURNAL for May 29. It is there given for the cementing of lenses, but that will give you the way it is used generally, and it may possibly answer your purpose. 2. We should advise you to try it. The object of the aluminium is to give extra hardness to the cement. We should think your best way of getting what you want would be to apply the gelatine in a fluid state, instead of attempting to cement a dried film to the metal. Whatever method you use, it is imperative that the metal must be thoroughly clean, that is, absolutely free from all traces of grease used in the polishing, otherwise the film will split off when it becomes thoroughly dry.

ALBUMEN AND COLLODIO-ALBUMEN.—Is there any actual difference between the collodio-albumen and the albumen processes, or is it only in the names? My reason for asking the question is this? In reading the details of the albumen process I see that the glass is coated with iodised collodion before the albumen is applied, and it appears to me that the sensitive film must be a compound of iodide of silver in collodion, and iodide of silver in albumen, so why is this called merely the albumen process?—INQUISITIVE.

The two processes are different. In the collodio-albumen process the plate, after coating with collodion, is sensitised in the silver bath, as in working the collodion process. It is then washed and coated with the iodised albumen, dried, and again sensitised in a silver bath. You will now see that there are two sensitised coatings on the plate—one collodion and one albumen. In the albumen process the collodion only acts mechanically as a substratum, as all the iodide is washed out of the film before it is coated with the albumen. The reason for using old iodised collodion for the substratum is that such collodion is of a more porous character, and allows the albumen to permeate it better than plain collodion would do. Collodio-albumen is more sensitive than albumen.

PEDLARS ACT.—I have been a photographer for over fifteen years, but now, unfortunately, I am in very low water. For the last year I have been getting my living, such as it is, by visiting the villages of Somersetshire and obtaining orders for taking portraits of the villagers. Being a good photographer, I supply better pictures than the general run of itinerant photographers, and keep my promises as to the time of the delivery of the portraits. In this way I find my work slowly increasing, as I visit the places periodically. One day last week I was stopped by a police sergeant, who asked to see my pedlar's licence, when I told him that I was a photographer. He then said that if he caught me again working without a licence he should take me before the magistrates. Will you kindly say if the law requires a photographer working as I do to hold a pedlars' licence? I may add that I only take a small deposit in the first instance, but with those I have done pictures for before I do not ask for one.—BROKEN DOWN.

Yes, the way you do your business certainly brings you within the Pedlars Act, and you require a licence. It is only quite recently that the police have troubled about itinerant photographers. This is probably due to large numbers of so-called "photographers," who are infesting country places and committing more or less fraud on the inhabitants.

INDUSTRIAL ALCOHOL.—Will you please inform me if there is any difference between industrial alcohol and the ordinary methylated spirit of the shops. I want some methylated spirit, but it must be free from the mineral spirit which I believe the latter contains.—T. WALTREV.

The ordinary methylated spirit contains 10 per cent. of wood naphtha and a certain percentage of mineral spirit. The indus-

trial alcohol contains but 5 per cent. of wood naphtha and no mineral spirit. To purchase this a licence from the excise is necessary. No charge is made for the licence, but a bond has to be entered into that the spirit is only used for the purposes the licence specifies. Then the spirit must be purchased direct from an authorised methylater in quantities, the minimum being, we think, ten gallons. The local Excise Officer of your district will give you all particulars.

**COPYRIGHT.**—I have had a photograph brought to me to make an enlargement from. It is stamped copyright. It is of the customer's mother, and I said that if the picture was copyright I could not execute the order. He said he knew nothing about any copyright in it, as he took his mother to the photographer's to have her portrait taken, and he paid for it in the ordinary way, and the prints were sent to him.—R. C. J.

If the facts are as stated, the copyright belongs to the son who paid for the taking of the portrait. Therefore, the picture is illegally marked copyright, and you may, of course, execute the order for the enlargement, or make any copies of it that may be required. It is illegal to mark a photograph "copyright" in which no copyright exists, as it claims a monopoly that is not possessed. In the case of patent, anyone who marks a thing patent when there is no patent in it renders himself liable to a heavy penalty. Some few photographers, we are aware, mark pictures copyright in which they hold no such right, but so far as we can call to mind they have, as yet, not been proceeded against for this illegality.

**CHONDRIIN.**—I want some pure chondrin for some experiments I am going to make. Will you please say where it may be had, and its price?—T. CHILDS.

Chondrin is not an article of commerce, and we do not know how you can obtain it. Chondrin is gelatine made from cartilage, and some gelatines contain it in large proportions.

**SALE OF INVENTION.**—I have made an invention (a new kind of apparatus which I think will prove of some value), but I have not the capital to put it on the market, or the money to spare for a patent. If I offer it to any of the large houses they will see what it is and perhaps exploit it without my getting anything for the invention at all. Any information you can give me as to how I may obtain some remuneration for the invention I shall be thankful for.—INVENTOR.

The best advice we can give you is that you obtain a provisional protection, which will only cost you one pound, and will give you invention protection for six months before the complete specification need be lodged. In the meantime you can show the apparatus to as many as you like, and negotiate for the sale of a patent for it.

**BELLOWS OF CAMERA STICKING.**—The bellows of my camera—a whole-plate one—when it is put away out of use for a week or two sticks together when opened, and, at times, I have a difficulty in separating the gussets. Can anything be done to prevent this, as I am afraid that the bellows will get damaged each time it is opened. Would oiling the bellows do any good?—G. W. ROBERTS.

We should certainly not advise you to apply oil to the bellows, which would make it messy to use, and, after a time, do injury. The best treatment will be to well rub the gussets over with French chalk each time the camera is put away. With this treatment, after a time, you will probably find that the varnish on the bellows will have lost its tackiness.

**BUILDING LAWS.**—I am having a studio 25ft. by 12ft. put up in the garden here for professional portraiture. A few days ago the town surveyor came, saw the building, and has since ordered it to be taken down forthwith, or proceedings would at once be taken. The studio is of wood and glass only, no brickwork. It is 6ft. from the back of the house, and 2ft. from the garden walls at each end. A friend tells me that the Building Act cannot compel me to pull the studio down, as it is not infringed. Another says that if I put wheels under the building that will get me out of the difficulty. What is your opinion?—QUANDARY.

Our opinion is that if the town authorities have condemned the building you will have to take it down. Different towns have different building by-laws, and one may fairly surmise that, according to them, the authorities are within their rights in ordering the studio to be pulled down. It would be of no use,

as your friend suggests, to put wheels under the building. The best advice we can offer is that you interview the town surveyor and learn from him if any modification can be made in the thing so as to conform with the local by-laws.

**INJURED STUDIO.**—I have the above premises on a seven-year lease—two still to run—I to do all necessary repairs. There is on the top of the house and much exposed. During a gale a few weeks ago the wind did much damage to the several panes of glass were blown in, and one sash bar was broken quite through. In fact, the studio is almost a wreck until repaired. I have seen the landlord and asked him to do the necessary repairs, as the damage was not due to fair wear and tear. He repudiates the claim, and says I must do all the necessary. As the damage was done by the wind, is not it classed as "an act of God," and he (the landlord) become liable to do the repairs?—POOR PHOTO.

We do not see that you can call upon the landlord to do the repairs. You hold the premises on a repairing lease, and it is to us that it was for you to see that the studio was kept in sufficiently strong state to resist the wind, even in a strong gale. Had the place been wrecked by, say, an earthquake, the result might be different. As it is, we surmise, the loss will fall on you.

**VARNISHING NEGATIVES.**—Will you please tell me if the varnishes sold for varnishing negatives, such as those the formulae for which are given in the "Almanac," can be applied with a brush. I find that when I pour it on, as directed, making the negative hot, I get as much on the back as the front, and nothing of what gets on my fingers and hands.—ALF. C. SYMONS.

The varnish may be applied with a broad camel-hair brush that will entail a great waste of it, as well as of spirit for drying the brush for future work. The simplest and most economical way of varnishing negatives is to flow the varnish over them in the usual way. It requires no special skill or knack. The difficulty has, probably, been due to the negative not being thoroughly dry before the varnish was poured on. Or, possibly, the plate was made too hot. If that was the case, the varnish would not flow freely over the gelatine film. The plate should not be made more than just luke-warm; then the varnish will flow freely, and, when the surplus is drained back in the bottle, the plate should be made as hot as the hand can well bear.

**MAGIC PHOTOGRAPHS.**—Will you kindly tell me how to make what are called magic photographs? A customer of mine has some shown recently at a children's party. A piece of paper, says, was shown on which nothing could be seen, but when pressed between sheets of damp blotting-paper a portrait, a grotesque picture, appeared, which was evidently a photograph. My customer wants me to supply him with similar pictures.—PROVINCIAL.

A print is made in the ordinary way, preferably on albumen paper, fixed and washed, but not toned. It is then put in a solution of bichloride of mercury until the image disappears, is again washed and dried. Some blotting-paper is saturated with a solution of hyposulphite of soda and also dried. To reproduce the image the blotting-paper is moistened with water, and the invisible photograph pressed in contact with it, when the image at once appears.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Method of preparing the half-tone block by direct exposure in camera or directly from a negative has been worked out by Mr. Payne. (P. 468.)

According to reports from several sources, manufacturers and dealers of photographic goods in Germany are feeling the effects of the war, and are leaving no stone unturned to get business from foreign markets. (P. 467.)

Professor G. H. Bryan has published a description of a system of calculating photographic exposures in which only numerical addition is employed. (P. 476.)

The Blenheim Club, which on Monday last transferred itself to the new Rooms, had a veritable house-warming in the shape of a dinner which broke out on the top floor. (P. 479.)

Self-portrait shutter release, a posing accessory, daylight loading, and photo-pendants are among the patents of the week. (P. 478.)

Dr. Sheppard's lecture (the second) on the chemistry of colloids dealt with the structure of gels and the phenomena of dialysis, which many colloid bodies exhibit. (P. 469.)

W. Scheffer has made a further microscopic study of the action of reducers upon the gelatine plate. (P. 472.)

The half-made reversing C solution would appear to be the secret of the fading stains on Autochromes. (P. 465.)

The recent annual report of the Patent Office shows that there has been a considerable abatement of the number of applications for photographic patents. (P. 465.)

## EX CATHEDRA.

### Permanganate Stains on Autochromes.

We have had several queries with regard to the prevention of stains produced by the permanganate reversing bath, and it appears that many meet with this trouble and endeavour to obviate it by the use of other solvent solutions. In our experience such stains are easily avoided by using fresh solutions only. A permanganate and acid solution that has been mixed for some little time stains very readily, but if the two ingredients are kept separate until the time of use then a stock permanganate solution will keep well for at any rate some weeks. After a month or so it will begin to produce stains even if the acid is only added just before use. The secret of success is then only to use a recently made up permanganate solution and to add the acid just before use. As regards other solvents, we are doubtful if there is anything that can be described as better than the one recommended by Messrs. Lumière. In our hands it has always worked excellently so long as we observed the precautions suggested above, and did not attempt to use it more than once.

\* \* \*

### 4,154 Photographic Inventions.

The twenty-fifth report of the Comptroller-General of Patents, Designs, and Trade Marks, which has just been issued, details noteworthy information regarding the progress of patented inventions. The latest available figures given show that the average number of complete specifications published each year in the class devoted to photography continues high. From the years 1855 to 1883 the average number of specifications published per year was only 16, whereas the quinquennial averages per 12 months for the first twenty years under the important Act of 1883 were:—1884-88, 89; 1889-93, 146; 1894-98, 161; 1899-03, 208. In 1904 the figures advanced to 232; in 1905 to 235, but in 1906 they fell to 206. The total patents affecting photography for 1855-1906 was 4,154; the average per year (1855-1906) 80. During 1907 the Patent Office dealt with 29,040 applications for patents of all kinds. There were 19,630 provisional and 18,893 complete specifications and 16,272 were sealed. Designs were registered to the number of 24,039 (applications totalling 24,928), and 6,255 trade marks were registered, there being 10,796 applications.

\* \* \*

### A New Photometer.

In view of our recent note on the Rumford photometer a modification of it suggested by W. Biegon von Czudnochowski in the "Illuminating Engineer" for April is of considerable interest. The writer does not seem to be aware of the advantages of the two-rod photometer, as the Rum-

ford photometer that he describes is a single-rod one, that he calls the "Lambert" or "Lambert-Rumford" photometer. In his modification he substitutes a diagonal square network for the rod, and arranges matters so that the shadows of the square apertures overlap and form a series of smaller squares. The shadows are received on a diffusing or semi-transparent screen, and a binocular viewing apparatus is employed so that the shadow image formed by the right-hand light source is observed by the left eye, and that formed by the left-hand light is observed by the right eye. It is claimed that a stereoscopic effect is produced, and that colour differences disappear when the lights are properly balanced. The reasons for this are not quite clear, and an analogy between this apparatus and the "Anaglyphs" of Du Hauron renders the matter even more obscure, but the writer claims for his photometer great sensitiveness, simplicity, and value for the comparison of differently coloured lights. As it can be used on a photometer bench it should be adaptable for photographic density measuring, and therefore it seems worth while to give it some attention. If it has all the advantages that its inventor claims it should be of considerably greater service than some of the photometric devices in common use. It is hardly fair to criticise the device from the very meagre description published, but we should like to point out that if the effectiveness of the photometer depends on the binocular blending of the differently coloured shadows, and this is the only idea that we can gather from the description, then the accuracy of the results will be open to question. The two eyes may differ in colour sensitiveness, and, moreover, colours do not blend binocularly in any very determinate fashion, and when they do blend they do not necessarily give a grey, as the writer seems to suggest. Possibly, however, we are misinterpreting his ideas and arguing from wrong premises.

#### Repairs and Leases.

We are continually receiving queries that show very clearly that photographers, like many other people, very readily get into difficulties through pure ignorance of their legal obligations. A correspondent last week complained that his studio, which he held on lease under the obligation to keep it in repair, had been damaged by a gale, and that the landlord expected him to put it right again. Naturally he would do so, but the tenant states that he asked the landlord to do the repairs as the damage was not due to fair wear and tear, from which we may conclude that he is under the impression either that he is himself liable to make good the effects of fair wear and tear or that the landlord is not. If he had taken the trouble to ascertain what obligations he incurred when he took the studio he would probably have found that the liabilities were exactly the reverse. The tenant is usually exempted by the lease from responsibility for anything that can be classed as fair wear and tear, while if he has entered into a general covenant to repair there is hardly any kind of damage, outside the fair wear and tear, that he cannot be compelled to make good. Even if he has not assented to any repairing clause he will still find himself liable to effect repairs unless he has a definite contract with the landlord to the effect that the latter will repair. The law does not show any particular tenderness for tenants who do not look after their own interests in these matters, and if lessees are not prudent enough to employ a solicitor when taking up a lease they may find themselves let in for undreamt of obligations in the case of any disastrous damage. A rough and ready but safe point of view for the tenant is that he may have to effect at his own expense any repairs that the landlord is not especially compelled by the lease to per-

form. The popular view is more or less the opposite of this, hence many fall into trouble. Everything depends on the wording of the lease, which cannot be scrutinised too carefully, for the things omitted may be of greater importance than those included.

\* \* \*

#### Building Laws and Studios.

A complaint that we very frequently receive relates to the cruel behaviour of local authorities who insist on the removal or drastic alteration of a fine new studio that the querist has just had erected. Such troubles are very easily avoided by proceeding in a business-like manner from the start. The building bye-laws vary in different localities, but a copy of them can always be obtained simply asking for it. If the building is erected in accordance with the bye-laws there will be no trouble, and there is any doubt as to their meaning and requirements it is only necessary to personally submit the drawings to the local authorities, who will in a few minutes point out any mistakes and give all necessary explanations. Owing to want of funds, it is impossible to build in accordance with the bye-laws, the only safe course to adopt is to submit drawings to the County Council, or whatever proper authority may be, and ask for special permission. If the erection is a small one and the proposals involve no obvious danger this permission will generally be granted. If, however, permission cannot be obtained for an 'irregular' building, there is no sensible course but to alter it and make it regular, or else abandon it. Attempts to dodge the laws, such as mounting the erection on a temporary structure, so that it may be claimed to be not a building, will fail, and may prove extremely expensive. Another and very common dodge is the attempt to run up the building when the authorities are not on the watch. This involves a heavy fine for not giving notice, in addition to other expenses, and though often attempted it seldom succeeds. The authorities are, or should be, always on the watch for such proceedings, and if they fail to see the irregularity it is fairly certain that some kindly person will inform them.

\* \* \*

#### Marquois Scales for Multiple Mounting.

A writer in a contemporary has suggested a method of trimming the vignettes on the mounts used in multiple mounting, and this is certainly worth trial. Practically all the Marquois scales used by mounters are draughtsmen's, though the writer does not seem to value or appreciate the use of the proper instruments. Briefly described, Marquois scales consist simply of straight drawing scales and a 60 degree set square. On the hypotenuse of the longest side of the set square an index mark or arrow is stamped, and if this side of the square is kept against the drawing scale, and lines are ruled by the longer of the two ruling sides, then the separation between these ruled lines is always exactly half the distance that the index point is from the scale. If, for example, we wish to rule parallel lines one-eighth of an inch apart, the scale is first adjusted so that one division comes against the index. The drawing scale is then ruled; the set square is slipped along the drawing scale for one-quarter of an inch, and the second line is ruled, the result being two lines exactly one-eighth of an inch apart. The instrument is very simple and extremely accurate. Any scale can be used and any 60 degree set square provided an index mark is placed on the edge. A scratch is sufficient, and a draughtsman can always find his own Marquois scales in a few seconds, though proper instruments are available upon the market at a price adapted to the innocence of purchasers. The advantages of such scales in multiple mounting are obvious.

curious that no one seems to have suggested their use. A large set square is, of course, necessary, and the one used is best if square edged, and of the same size as the set square.

**Trade in Germany.** According to a report (just issued by the Foreign Office) by the British Consul on the trade of Leipzig and Chemnitz, for the year the branches dealing with the manufacture of photographic apparatus and requisites were fully occupied up to the middle of the year. After this, the bad weather did trade unfavourably, and the stock in hand was only cleared off by means of concessions made to buyers. There has been a large over-production of photographic requisites and printing paper, which naturally lowered prices. The system of payment by instalments for articles required for amateur photography continues to cause loss of trade, and the manufacture of studio instruments has been hampered by the institution of photographic branches in emporiums, whereby a number of professional photographers have been thrown out of work. The trade in the manufacture of photographic apparatus and requisites has also during the last months of 1907, the business in photographic reproductions, which is chiefly dependent on the export of picture postcards, having to maintain itself against the crisis in the American market; the duties of other countries are also unusually distasteful, and the export of photographic articles has therefore still more diminished. Further, British American dry-plates, at equal and at even higher prices, have competed successfully with German goods, this being attributed to the low duty in Germany and to the good quality of the foreign output.

#### THE MANUFACTURE OF PHOTOGRAPHIC APPARATUS AND MATERIALS IN GERMANY.

A yearly report of a leading photographic apparatus manufacturing firm, in Dresden, Germany, which has just been published, affords some insight into the present state of the photographic manufacturing business in that country. The profits of this company for the past working year amount to £2,000 15s. (40,015 mark.). It has been decided to invest this sum in the improvement of machinery and in raising the general efficiency of the factory; consequently the shareholders are not to receive any dividend. On account of the slight increase of capital which the published accounts show, this small profit on the year's working leaves much to be desired, especially when one takes into consideration the comparatively large sum invested. Though there is no particular cause for alarm, the directors, nevertheless, seem to consider that some explanation is necessary, and they conclude their report with the following remarks, to which special attention might be called, since they doubtless express what is felt in many another manufacturing business outside of Germany: "If the outlook for the photographic industry is not a generally favourable one, there is still, however, hope that there will be some improvement in the future, especially as competitors will eventually be forced to see that underselling and at the same time increasing the amounts of discounts given must ultimately find its natural bounds; especially in those markets where the demand for goods leaves nothing more to be desired. We hope that in the business year upon which we are entering, should no unforeseen accidents disturb our existing arrangements or other unexpected hindrances occur, to show a much more satisfactory result." In connection with this same subject it may be worth while drawing attention to an article which has just appeared in a German photographic contemporary urging German manufacturers of apparatus and photo-

graphic materials to make a bold bid for the Oriental market, especially Greece. The writer even sees prospects of improving the markets for these goods in the whole of European and Asiatic Turkey, in the islands and lands lying to the East of the Mediterranean Sea, in Egypt and in various parts of Northern Africa. Though English and American goods are at present on the market the business is for the most part in the hands of the French. The reason for this is not only because the French language is spoken and generally understood in these countries, but the French business men have flattered the merchants by learning their language, so that they may speak and correspond with them in it. One point to which this article calls attention is the great advantage of having the price lists, or other commercial literature intended for circulation in these countries, printed in the language of the country, and the prices to be given in the current coin of the particular district. Attention is drawn to the fact that the resident Consul in any or all of these countries can be of great service to firms in getting addresses of commercial houses interested in photographic or other goods; and later, when business relations are about to be established, the Consul is the most reliable source to go to for information concerning the financial position of the house and other particulars regarding it.

There are various signs and indications that German firms engaged in the manufacture of photographic apparatus and other similar articles will in the near future be even more energetic than they have been in the past. One reason for this is that the struggle among themselves is becoming keener and keener, since new firms are constantly being established, and the most natural outcome of this is that markets abroad, which have been more or less commanded by British and American manufacturers, are likely to feel more keenly the pressure brought to bear upon them by German representatives. We do not mean to suggest by these few remarks that German goods are likely to catch all the markets, to the detriment of British goods which are already in popular demand. That can only happen if the British manufacturers fail to grasp the situation before it is too late. Therefore, so far from posing as alarmists, we merely mean to suggest which way the wind is blowing; to give what we feel is a timely warning, and at the same time we hope we may be instrumental in bringing the attention of new firms to what promises to be a good field for their goods. No doubt there is room for all; still, it is well to keep in mind the old motto that "the early bird catches the worm." And what is of equal importance to the business man is the fact that when he has secured his market he must keep a constant eye on his own interests in it, study its changing moods and requirements, and do all in his power to keep his hold and influence on what he has secured.

One peculiarity of the German manufacturer is that he seems to be more anxious to secure foreign markets than he is to monopolise the home markets. Various reasons might be given for this characteristic of nearly all German businesses, but to give some of these reasons would launch us into a more or less political subject entirely out of our province. Still, the fact remains that in order to secure foreign markets German manufacturers often sell their goods abroad at very much lower prices than one can buy the same goods in Germany, and that, in spite of the increased costs of carriage and other incidental expenses necessary to the placing of the goods in the hands of the consumers.

Of late the somewhat coercive methods employed by German manufacturers in supplying their own markets at home have caused much heart-burning. Some of the larger firms are over-capitalised and are working at a loss. This has led to the attempt to form rings, or combines,

which have for their object the cutting out of the smaller manufacturers, and the raising of prices. So far the attempts to monopolise the markets have been mismanaged and some bungling has resulted, causing the various parties to be more or less divided against each other. Professional and amateur photographers have closely followed all that has been going on. They have decided not to wait until they see if order is likely to come out of the chaos, but are preparing themselves to do battle against the manufacturers. Indeed, there has already been one direct outcome of this activity in the shape of a general union of most of the amateur photographic societies in the German Empire. This Union was accomplished in February of this year, and is composed of thirty-five

societies, with a membership of 2,791. It held its first general meeting in Berlin in the middle of April. At the opening gathering the President, Captain Kiesling, explained that the object for which the Union existed was not to attack the manufacturers, but to protect the interests of amateur photographers. The new Union established its headquarters in Berlin, though it has arranged to hold its yearly meetings in different towns within the Empire attended by delegates from all the various States.

Apparently the amateur photographer in Germany possesses an interest in the politics of his hobby which can rarely be discerned in his British prototype. But it may be doubted whether either would take a serious part in the event of a general trade dispute.

## PROCESS BLOCKS BY DIRECT EXPOSURE IN THE CAMERA.

A REVOLUTION in photo-engraving is promised by a new process or method of block-making, which, if not yet fully perfect, is certainly a step towards a goal which process-workers have been trying to reach, namely, the production of a photo-engraved

From negative. With 133-line screen.

plate in the camera without the intervention of a photographic negative. Such a system has obvious advantages in point of economy and speed of working, and therefore considerable in-

From negative of picture. With 65 line screen.

terest attaches to the announcement which we make of a process of which more is immediately to be heard.

The process, as we now roughly outline it, has been worked out by Mr. Arthur Payne, of Newcastle-on-Tyne, well known

as a practical worker in photography, an easy writer on technical subjects, and the technical manager of a dry plate works—a combination of faculties not often met with. The process which is to bear his name is already the subject of application for a patent, and therefore our description of it must be general. Suffice it to say that the process dispenses with the screen negative, and substitutes for it a metal plate, on which, in the camera, the screen image is formed. The plate is then

From negative. With 65-line screen.

An ordinary half-tone impression from a block of this same subject will be found in "E.J." July 6, 1906, p. 531.

treated as to form an efficient resist for the etching bath. Mr. Payne gives fourteen minutes as the average time in which one man can produce a plate (ready for etching) from a negative original. The production of the resist does not involve the use of electric arc light, as in the present method of enameline printing. The apparatus necessary for the operations amounts only to a developing dish and a "whirler," and the process, moreover, has the advantage of being worked in the cold, so

the zinc of the plate is not destroyed by heating, as is the case with the usual enameline processes. As far as the process affects the photo-engraver, it may be said

Portrait of Mr. Arthur Payne. Block prepared by the new process.

the prepared metal plates should be marketable at about the price which is now paid for metal and dry plates. The process-

worker thus pays no more for his material, while he saves time, and the cost of polishing, of fish-glue, of electric light, etc.

The examples shown herewith are from half-tone blocks by the new process, and, though only Mr. Payne's amateur experimental results, they show the "workability" of the process. Moreover, these results are obtained on hand-coated plates. As regards the adaptability to work of different classes, it is found that the process is suitable for screens up to a fineness of 133 lines per inch. It is also fitted for intaglio and relief line work in addition to half-tone printing.

The original in the case of each subject here shown is a negative. The system also includes the making of a positive "process" impression from a positive print, though this process is more difficult and takes a longer time (20 to 25 minutes) than when preparing a positive process impression from a negative.

In addition to its use in process work, this method can be applied to the production of engraved metal plates for use as name plates, illuminated brasses for churches, ship work, engraved dials, engineers' name plates, furniture goods, etc., by photographing printed matter, or line sketches, direct on to the metal plate, which is then etched and the intaglio marks filled in with coloured wax.

It ought also to be an economical process for the production of engraved glass and engraved flashed glass designs much used now by railway companies, restaurants and hotels, tram car advertisements, and similar uses.

The process probably could also be used by calico printers and wallpaper printers.

## THE CHEMISTRY AND PHYSICS OF COLLOIDS.

The following abridged text of the second Bolt Court lecture by Dr. S. E. Sheppard on the Chemistry and Physics of Colloids is more particularly with the properties of gelatine and similar bodies. The third lecture was delivered last evening. "B.J.]"

In the last lecture I endeavoured to present a general, but necessarily rough, picture of the field of colloid chemistry. Dealing with colloid solutions, or hydrosols, we saw that these consisted of extremely fine suspensions of particles in the solvent, the particles being electrically charged. The aggregation of these particles into a solid coagulum may be brought about by a variety of physical and chemical agencies; in some cases a coagulum is redissolvable, in others not. In the first case we are said to be dealing with "reversible colloids," in the latter "irreversible." Furthermore, it was shown that certain colloid solutions—notably those of organic colloids—possessed the property of "setting"—i.e., on cooling they form a gel or solid, partaking of the properties both of solids and liquids. Because these gels are of such great importance both for photographic and photo-mechanical processes, we must consider them in somewhat greater detail. But first a few points touching the preparation and investigation of colloid solutions should be noticed.

### Preparation of Inorganic Hydrosols.

*By Metathesis or Chemical Interaction.*—This method, with conditions giving a precipitate under ordinary conditions, gives a "hydrosol" if the reaction is retarded—e.g.,  $\text{AgNO}_3 + \text{KBr} = \text{AgBr} + \text{KNO}_3$ , one electrolyte in slight excess. The electrolyte may be removed (a) by washing out, which explains why in precipitates pass through the filter unless washed with water holding electrolyte; (b) by dialysis—(A variety of membranes may be used for dialysis, according to the nature of the liquid—pig-bladder, purified with alcohol, may be used, also parchment of colloidion); (c) by filtration—(Although the colloidal particles pass through ordinary filter paper, they may be removed by earthenware filters of the kind used in bacteriology,

and some conclusions as to the size of the particles may be drawn from their behaviour—cf. R. Zsigmondy, *Zur Erkenntnis der Kolloide*, p. 120. Recently H. Bechold has introduced specially prepared filters, consisting of filter paper impregnated with hardened gelatine or other colloid, which may be used for the separation of colloids).

(2) *Hydrolysis.*—Another general method, by which the insoluble hydroxides may be prepared, is by the hydrolytic dissociation of the salts. The salts of weak bases are acted on by water according to the scheme,

the solution becomes acid, and the hydroxide remains in solution or suspension. The acid may be partially removed by dialysis. Conditions favouring the hydrolysis are increased temperature and dilution.

(3) *Action of Reducing Agents on Salts of the Noble Metals.*—This was the method used by Carey Lea to prepare soluble, allotropic silver. By its means, in one form or another, most of the noble metals may be prepared in this state—e.g., silver with the reducing agents used in photography (ferrous sulphate, pyrogallol, amido-phenols). In the presence of "Schutz-kolloide," or organic colloids in small traces, which exert a stabilising influence, the preparation is much more certain. Gelatine is especially efficient.

(4) *Peptisation of Gels.*—Many gels have the property of liquefying with quite minute quantities of an electrolyte and giving the hydrosol. The name is given owing to the analogy with pancreatic digestion which occurs according to the scheme

From this analogy it has been proposed (B. Szilard, *Beiträge zur Allgemeine Kolloidchemie*) to term the peptising electro-

lytes "pepsoides." Thus silicic acid gel was shown to be peptised by minute quantities of caustic soda by Graham.

(5) *Electric Dissipation or Zerstäubung*.—It was shown by Bredig that if a small arc is passed between poles of a metal in well-cooled aqueous solution, the particles from the cathode form a colloidal solution. By this means hydrosols of most of the noble metals may be obtained, and Svedberg has obtained solutions of the light metals in organic solvents.

### The Ultramicroscope.

The formation of colloid solutions by the dissipation into dust of the cathode is another argument in favour of the view that these consist of suspensions of fine particles, albeit ultra-microscopic. But it is possible to bring this to a direct test, for, although the particles are too fine to be seen themselves, they may be rendered visible. There is a theoretical consideration which expresses the practical limit to our optical division of things seen. The condition that two points should be optically resolved by a microscope system is given by the formula

$$e' = \frac{\lambda}{2n \sin \alpha} > \frac{\lambda}{2a}$$

where  $e$  is the distance between the points required to be separated. This formula is based on the application of the theory of the grating made by Helmholtz, Rayleigh, and notably Abbe. In explaining the terms, we may suppose the space between the object and objective entirely filled by homogeneous matter having a refractive index  $n$ , then  $\lambda$  represents the wave-length of light for the radiation employed. If  $\alpha$  is the angle subtended by a point of the object on the lens of the objective, then  $n \sin \alpha$  is called the "numerical aperture" N.A. =  $a$ . It will be seen that we can increase the resolving power—i.e., make  $e$  smaller, either by lessening  $\lambda$  or increasing  $a$ . The former method is limited by our limited range of vision through the spectrum, but a great extension may be obtained by using photography with ultra-violet light. The second condition, increasing the N.A., is limited by the refractive index of the materials we can employ. In the best dry objectives, where  $n$  is the index of the air,  $\alpha$  reaches 73 deg., for example, and the numerical aperture is 0.95. With cedar-oil immersion objectives, index 1.515, objectives may be made of numerical aperture 1.3 or 1.4.

But the conditions become easier if, instead of proposing to study, under their true forms, the objects considered, we merely desire to render them visible. The sole condition, then, is that the object to be seen be sufficiently remote from others, and that it be self-luminous. Such a point will have in the plane of the image a small field of diffused light standing out against a dark background. The eye will always see it, provided the intensity of this light be sufficient. It is thus that we see the stars, even with the most powerful telescopes. With the naked eye we only see them by night, because the general illumination of the sky in daylight drowns their feeble radiance. Now, just as the telescope, by concentrating more light, enables us to see more stars than with naked eye, so we can employ the microscope to render visible ultra-microscopic objects by concentrating on their images more light than they would give directly. Now, although few objects are naturally self-luminous, we can make them so by concentrating an intense beam of light on

Fig. 1

them, when they scatter or diffuse this light in all directions—i.e., behave as light sources, as you see dust in a sunbeam. Just

as the dust is best seen in a darkened room, so with the scope we require "dark field" illumination—i.e., *no illuminating beam must penetrate into the objective used for observation*. Several methods have been evolved to fulfil this condition: the simplest in theory is by *lateral illumination*; objective B concentrates an intense beam on the specimen which is viewed by the second objective A. This method, refined, is that employed by Siedentopf and Zsigmondy in their first apparatus.

Another method has been evolved by Cotton and Montanari, French scientists. The principle is as follows:—Illuminate the preparation, contained, as usual, between slide and cover-glass, by a sufficiently oblique beam coming from below, the rays of this will undergo total reflection on the upper face of the cover-glass at the air surface, and will be thrown back, none penetrating the objective. The particles on the path, however, will diffuse the light, sending it in all directions, including the microscope. When viewed in such an instrument, the particles appear as small spheres of varying intensity of illumination and colour. They move in zigzag paths, like a swarm of gnats on a fine day. These movements are the same as the Brownian movements of fine microscopic particles.

### The Structure of Gels.

In the last lecture it was stated that gels consist of two portions, one part being a semi-solid wall of the colloidal other (enclosed in the former) a colloidal solution of the other in the solvent. Suppose A be the colloid, B the solvent, we have in the gel walls, or partitions, consisting of much A, little B, enclosing a solution, much B, with little A. The sponge-like structure of gels can be demonstrated in several fashions. It explains certain phenomena in photographic reactions. The cellular structure of gelatine may be shown by coagulation with tannic acid and microscopic investigation, as done by Bütschli. The inhomogeneity is made evident by filling the cells with a substance having a different refractive index. This is shown in the case of gelatine films rapidly dried in alcohol, which frequently show an opalescence, as Lüpcke has pointed out.

Bütschli found that the sponge or foam structure was microscopically visible with agar jelly and coagulated albumen, but not with gelatine. If the albumen is dried, it becomes yellowish with a glassy transparency, and the structure is no longer visible, showing that the walls have fallen together in the desiccation.

Bütschli treated gelatine with absolute alcohol, and dried it on a cupboard at 54 deg. C. The gelatine became white and opaque with gas bubbles, and showed, with a magnification of 3,125 (sponge structure, the elements being of some  $.7 \mu$  = 1-1,000 mm.) in diameter.

Hardy has also shown the cellular structure of gels microscopically under certain conditions—viz., albumen, coagulated with heat, by sublimate, bichromate; silicic acid by hydrofluoric acid, by sublimate, formaldehyde, or bichromate. Gelatine showed a closed network of cells, with concentrations above 7 per cent., when fixed by alcohol or sublimate. But with smaller concentrations, or by the long action of excess of formaldehyde, an open network similar to that of albumen is obtained.

Thin collodion films, after treatment, also show a definite structure in the ultramicroscope. When very fluid collodion are solidified they frequently become white, and the foam-structure can be observed microscopically; the opalescence is attributed by Bütschli to air; the diameter of the elements or pores is  $.8 \mu$ , of the walls, in the mean  $.2 \mu$ .

Cellulose, celluloid, cotton, etc., possess a similar fine cellular structure. This porous formation gives a plausible explanation both for the phenomena of swelling and for the easy diffusion of substances in swollen gels.

### Membranes.<sup>1</sup>

Membranes may be defined as film-like, extended, solid bodies, subject to all the actions under the influence of electro-colloids, temperature, etc., found for the mass, but showing specialised phenomena, when, for instance, separating two fluids. They may be formed by the action of time, without solution of the milieu, on the surface of colloid solutions, at contact surface of reacting solutions, or by deposition. When separating two fluids they may be able to alter the equilibrium between the two in quite special fashions; in this way they act as regulators and valves in organised nature.

### Swelling Phenomena.

It is understood the taking up of fluid by a solid substance without any obvious "chemical" reaction, in the sense of the law of constant proportions. The increase in weight of the system is generally accompanied by an increase in volume. We must distinguish between—

Imbibition by a porous mass with preformed air-filled spaces as with pumice-stone: capillary imbibition.

A porous mass takes up water into preformed hollows, and is filled with a fluid, by endosmosis: imbibition by endosmosis.

A homogeneous mass free from pores takes up fluid by osmotic imbibition. It is questionable if this last category is necessary, if we consider that gels of the nature of gelatine consist of porous masses.

In the first case the swelling depends on surface tension phenomena, in the second we have osmotic effects. For the third or true swelling the following principles have been ascertained:—

A body which can swell can only take up a certain maximum quantity.

This maximum is dependent on the chemical nature of the body, on the fluid, the temperature, and on the viscosity of the fluid.

The swelling is accompanied by an evolution of heat.

The total volume of the swollen substance is less than the sum of its original volume and that of the fluid taken up.

The swelling and its opposite, contraction, depend to some extent on the surface tension between the substance and the surrounding fluid.

Lehmann<sup>2</sup> has investigated the influence of temperature on the velocity of swelling, and finds for the quantities of water absorbed by one gramme of gelatine at various degrees Centigrade:—

Temperature....	1°	3.4°	9°	20°	30°
Water.....	2.43	2.2	3.48	6.28	9.48

The increase in velocity is probably due to the lessened viscosity of the water. Various formulæ have been proposed to express the rate of swelling, but they depend on the mechanical division of the substance. Interesting experiments have been carried out on the swelling of gels in salt solutions. If we arrange them according to their capacity to favour the swelling or hinder it we have—

Barium sulphate, sodium tartrate, sodium citrate, sodium acetate (alcohol, dextrose, cane sugar),

Water,

Sulphates of potassium, sodium, and ammonium, sodium chlorate, nitrate, bromide.

With a solution of salt, and plates of glue, it was found—

The increase of weight is due to the taking up both of salt and water, but the proportions do not remain the same as in solution.

The taking up of water increases at first with increased concentration of the salt solution, reaches a maximum, and then sinks as the concentration still increases.

(3) The amount of salt taken up increases fairly proportionately to the concentration.

(4) A gel already swollen with water takes up more salt than water.

Generally the influence of salts is found to run parallel with that which they exert on the setting power. (See Lecture I.) Wolfgang Ostwald has typified the action of varying concentrations on the physico-chemical properties of colloids by the following schematic curves:—

Fig. 2.

### The Theory of Photogravure Etching.

Dr. E. Lehmann<sup>3</sup> has applied these results in colloid physics to explain apparent anomalies in photogravure etching practice. It is known that the velocity of etching decreases with increased concentration of the etching bath, and increases with its temperature; further, that the addition of alcohol slows the action. It has been suggested that this phenomenon is to be explained by considerations of tanning and diffusion. It was supposed that stronger iron chloride solutions tanned the film to such an extent that it became impermeable to the etching fluid. Lehmann points out that this is improbable in that the film has already been tanned by the action of light; such a subsequent tanning may take place, and is sometimes employed in practice, but it would in this case show itself in the thinnest portions by restraining the etching there, whereas these are still attacked by the concentrated solution. To this may be added that from the researches of Lüppo-Cramer on the tanning of gelatine by iron salts, that conditions favouring their hydrolysis, as dilution, favour the tanning action.

Another explanation was based on a supposed slower diffusion of the stronger solution. But this is contradicted by the general law of diffusion, which states that the rate of diffusion is proportional to the concentration gradient. Concentrated iron solutions should, therefore, diffuse faster, and Lehmann found that this was actually the case for concentrations such as are employed in etching.

Actually, Lehmann finds that a dilute etching solution does not really work faster than a concentrated one; it only begins to etch—i.e., to dissolve—the copper sooner, and from the time of starting concentrated solutions etch at least as fast as the more dilute.

Lehmann applies the laws of swelling treated of in the foregoing. Two separable processes take place, the imbibition or swelling, then the osmosis or diffusion of the etching salt, which attacks the copper. The swelling is not proportional to the time, but gets slower as the maximum is approached. The thinner the film, the faster this maximum is approached, and hence the commencement of etching. Hofmeister found that a layer of .2 mm. thickness reached its maximum in five minutes, one of .7 mm. in sixty minutes. And the smaller the absolute thicknesses, the greater do these differences make themselves felt. In heliogravure the thicknesses vary between .015 mm. and .005 mm. As the maximum difference is only .01 mm., only such a rapidly varying condition as the attainment of maximum swelling will explain why a graded etching is possible; differences in the diffusion time can hardly come into consideration with such thin layers, which is supported by the following:—If a copper plate is.

<sup>1</sup> H. Zangger. Vierteljahrsschrift d. Naturforschenden Gesell. in Zürich. p. 501.  
<sup>2</sup> Ann. Phys. 1885 (3) 25 145-153 1885).

(<sup>3</sup>) Zeitschrift für Reproduktionstechnik. 1907. IX. p. 54.

brought immediately after development of the relief and still wet into the iron chloride, this etches it almost immediately, and there is practically no gradation. It is suggested that the partially dried plate might be allowed to soak in water first to obtain softer results from very hard originals. If the swelling is hindered by alcohol, no etching takes place.

When salt solutions are absorbed instead of water, the con-

ditions are more complicated (see foregoing). With treated solutions, especially of hygroscopic salts, the decreases with increased concentration owing to the action of the salt molecules. It is obvious that with iron this effect will be very pronounced, and in this is to be found an explanation of the slower action of concentrated solutions.

S. E. SHEDDEN

## FURTHER RESEARCHES IN THE ACTION OF REDUCERS

DR. STÜRENBURG has recently stated that an alkaline solution of ferricyanide of potassium, reduces in a different manner from the Farmer reducer made up in the usual way. The alkaline solution is stated to act in a more delicate way. I therefore made up a solution in accordance with Dr. Stürenburg's formula, and applied it to the reduction of negative plates. Sections of these films show no difference in local action between the alkaline and the ordinary ferricyanide solutions.

Fig. 1 is a section of a film reduced with the ordinary Farmer

reducer. Next, several plates were exposed for an equal time under the same conditions, developed, fixed, washed, and dried; and were then reduced; some with the usual Farmer reducer, and others with the alkaline solution of Dr. Stürenburg. They were reduced in solutions until there was an equality of intensity in the (most strongly lighted) places. These experiments showed that the action of the alkaline and of the ordinary reducing solution was identical. The conclusion arrived at from the identity of local action in the first experiment was thus confirmed.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

reducer. We see here the sharply contrasted border of the action which I have formerly described as belonging to the Farmer reducer.

Fig. 2 is a section of a film reduced with the solution made strongly alkaline.

So far as we can see from the microphotographs, this solution has acted in exactly the same way as that which was not made alkaline. According to these photographs it follows that the addition of alkali changes nothing in the action of the Farmer ferricyanide reducer.

Figs. 3, 4, and 5 are representations of photometer negatives, showing the results described.

Fig. 3 is the plate before reduction. Fig. 4 is the plate after reduction with the ordinary Farmer reducer, and Fig. 5 is the plate after reduction with the alkaline ferricyanide solution, according to Dr. Stürenburg.

All my experiments have been made with Agfa plates. I have used both the acid and the ordinary fixing baths, and have employed

various developers. Some of the plates also were treated with various hardening solutions. In all cases the result was the same—namely that the recommended addition of soda to the solution made no perceptible difference in the actions. It is possible that certain kinds of plate might yield another result. I, however, have not succeeded in discovering any influence of the alkaline addition in causing a harsher or more delicate action of the reducer.

Dr. Lüppo-Cramer has, as is well known, shown that the addition

of sulphocyanide of ammonium to the ammonium persulphate solution causes it to act in a similar harsh way as the Farmer reducer. It is worthy of note that in this case the film section (Fig. 6) gives a similar

Fig. 6.

Fig. 7.

Fig. 8.

Fig. 9.

Fig. 10.

Fig. 11

Fig. 12

image to that shown by the ferricyanide reducer. The harshly working permanganate of potash was also investigated by means of sectional inspection. This section also (Fig. 7) shows the harsh edged action which was to be expected. It may be stated generally that the harsh working local action of the reducing agents, displayed in Figs. 1, 2, 6, and 7, is accomplished by a solvent action, that is rapid in proportion to their diffusibility.

Dr. Lüppo-Cramer also states that the black, fully developed grain of the strongly lighted parts of the film behave in a different way in the ammonium persulphate solution from the weakly lighted parts.

Figs. 8, 9, and 10 confirm this statement, and also give for the first time a graphic representation of this noteworthy fact.

show a closely united crystalline formation. Those that lie consist of extremely fine grained separate structures. (Note: minute detail of the negative is somewhat lost in the reproduction.)

The grain in the weaker lighted parts behaves in quite a different way. It is for the most part left unaltered; only at its outer edge we see delicate ring-shaped formations (Fig. 10), which, from an optical behaviour, appear to be highly refractive crystalline. In the weakly lighted places there is no essential difference observed between the upper and lower-lying granules. Apparently the ammonium persulphate is not able to dissolve the developed grain in the weakly lighted (exposed) places, in time sufficient to dissolve the black masses of the strongly lighted parts. These parts

Fig. 13

In these cases a plate was exposed under a photometer scale, and after full development, fixation, and washing, was treated with the ammonium persulphate reducer for so long a time, that the darkest circles had become almost as transparent as the lighter ones. In the previously darkest circles a characteristic brownish coloration then showed itself, whilst the less lighted circles retained their original colour.

Figs. 8 and 9 are representations of the grain in the strongly lighted parts. In place of the black developed grains we see delicate brownish coloured formations. In many of these, especially in the deeper parts of the film, we can see a fine-grained structure. Here and there we see in the remaining undissolved parts of the grain small black portions showing this structure, and lying more in the upper than in the lower stratum.

The difference between the upper (Fig. 8) and the deeper lying (Fig. 9) granular remnants is very marked; whilst the upper granules

Fig. 14.

make it appear probable that the building up of the grains in the weakly lighted places is different from that of the strongly lighted places. In the latter the grains lying near the surface behave differently from those that lie deeper; in the weakly lighted places there is no difference to be seen between the upper and the lower-lying granules. The fragments of the grain in the weaker lighted portions appear to build themselves a kind of protecting wall against the penetration of the ammonium persulphate solution. It was noticed that the strongly lighted places were, after treatment with ammonium persulphate, no longer soluble in hot water, whilst the weakly lighted places that remained black after reduction were easily dissolved in water that was only warm.

Figs. 11, 12, 13, and 14 show precisely the same places before and after reduction with ammonium persulphate.

Fig. 11 is a strongly lighted piece full of grain before reduction. Fig. 12 is the same piece after reduction by ammonium persulphate.

Fig. 15.

Fig. 16.

Fig. 17.

Fig. 13 is a weakly lighted piece from the same negative before reduction, and Fig. 14 is the same piece after reduction. Naturally, except for the exposure, all the experimental conditions for the two portions were just the same, since they were all portions of one and the same plate. It is to be observed that in the weakly lighted parts there is no change in the grain to be seen. The phenomena exhibited in Figs. 8, 9, and 10, only became noticeable after a longer action of the reducer.

In the course of my experiments I was struck by the following re-

sult and the thin films upon the slip of microscope glass. The ammonium persulphate solution acted in a remarkable degree, more slowly on the thin films than on the original negative. When the action on the grains in the strongly lighted parts of the original negative had become very decided, those in the strongly lighted piece that had been taken from the same negative and spread thinly on the microscope slip, showed no trace of change. Naturally, the grains from the more weakly lighted places that had been spread thinly on the glass were also not attacked. The slip was now left for a whole night in a strong solution of ammonium persulphate. During the night a reduction took place, both of the weak and of the strongly lighted portions. The strongly lighted grains showed a materially greater loss of substance than the less exposed ones. This is shown, not so clearly, however, in the pictures, since the continued action of the ammonium persulphate solution had dissolved a part of the gelatine, so that the formerly swelled film had settled down, and there is an appearance of an increase in the number of the grains. Figs. 15 to 20 are the result of this set of experiments. Fig. 15 is the grain

Fig. 18

Fig. 19

Fig. 20

Fig. 21

Fig. 22.

in the weakly lighted part. Fig. 16 is the same place after a time of reduction that sufficed in the case of the strongly lighted place in the original negative to render it very transparent. It will be seen that in these grains (Fig. 16) no change is observable. Fig. 17 shows the same piece after twelve hours' immersion in the strong solution of ammonium persulphate. It will be seen that the original configuration of the grains is very well maintained. The black constituent of the grains, however, is almost entirely gone, but there is left a framework of small crystalline bodies which maintain distinctly the original shape of the grains. Unfortunately, in the reproduction the details of the individual character and the grain formation have been largely lost.

Figs. 18 to 20 show grains in the strongly lighted part, 18 before, and 19 after, a stay in the reducer, which, in the case of the most strongly lighted circle in the original negative, sufficed to cause it to become almost as transparent as the least exposed part.

Fig. 20 is the same portion after a night's immersion in the reducer.

able result. In order to have as thin a film as possible I dissolved warm water, from a finished and washed photographic negative, a film from a dark and one from a light circle, and spread them in films on to a slip for examination and microphotographic reproduction during the various stages of reduction. For comparison I used simultaneously in the same solution the photometer negative,

As the film, owing to a partial solution of the gelatine, had considerably settled down, it looks like being fuller of grains. The individual grains can be seen to have become noticeably more delicate. This settling down can also be very clearly traced in Nos. 16 and 17. That the portion of the film in these figures is the same is beyond question. We see in Fig. 17, besides those which were already present, some grains which appear to be newly arrived. For example, the grains numbered 1, 2, 3, and 4. That these grains have actually come into view through the settling down of the film on the stage of the microscope, we see clearly in the grain numbered 1. This is already visible, though fainter, in Fig. 16.

In the image reduced by ferricyanide, characteristic foundation formations can also be seen. These are, however, so delicate that they cannot well be seen in the ordinary way.

Fig. 21 shows the plate grain before reduction, and Fig. 22 shows the same place after such a powerful reduction by the ordinary Farmer reducer, that, when held against a well-lighted white background, it appeared as clear as glass. Fig. 21 is the same piece as Fig. 22, as can easily be decided by comparison of the two pictures. It will be seen that the delicate remains of the granules show distinctly the configuration as seen before the reduction. The image

of No. 22 was photographed by light of wave-length  $f$  to 400.

In the foregoing experiments it was necessary, when dealing with magnifications of 2,000 diameters, to be able to adjust the plate exactly the same place on the stage of the microscope, at various intervals of the treatment. Besides all the care on the part of the operator, the appliances are essential. It is my pleasure to tender again my best thanks to the Zeiss establishment for the very excellent apparatus which, in the most obliging way, was placed at my disposal. It enabled me to succeed, even when dealing with magnifications of 2,000 and still greater diameters, in re-adjusting exactly the plate in the same position on the stage. In the foregoing graph, Fig. 23, for instance, it was almost impossible to say positively whether the same part of the object was actually in the field of view. The fitting of the objectives to the microscope proved also to be such a task that I was able at intervals to apply the microscope to quite a different purpose, and yet, after replacing the suitable objective, continue my researches without further adjustments.

All the photographs except that of Fig. 10 are enlarged 6,000 diameters. Fig. 10 is enlarged 6,000 diameters.

DR. W. SCHREIBER.

## THE INDEX METHOD OF CALCULATING PHOTOGRAPHIC EXPOSURES.

The following article, which we quote from the current issue of our contemporary, "Knowledge," deals with a method of calculating exposures, which, as the author states is quite familiar to users of logarithms. The "logarithm," however, has a formidable sound in the ears of non-mathematical persons, and therefore the explanation of the same system given by Dr. Bryan (who is Professor of Pure Mathematics in the University of North Wales) may be commended for its absence of all difficult symbols and formulæ. Eds. "B.J."]

THE exposure required to take an ordinary photograph, such as a landscape, with a hand or stand camera, depends at least on the following four factors:—

- (1) The light value.
- (2) The stop employed.
- (3) The subject.
- (4) The speed of the plate.

Of these factors the light value may, of course, be determined by an actinometer, but if calculated independently, it depends essentially on:—

- (1a) The altitude of the sun, which again depends on the time of year, time of day, and latitude of the place;
- (1b) The state of the atmosphere, whether clear or cloudy.

In order to simplify the multiplications and divisions required in taking account of these factors, various exposure calculators, based on the principle of the slide rule, have been put on the market. Unfortunately, however, a slide rule with a single movable scale cannot perform a multiplication or division sum with more than three factors, and we find that one of the calculators in question only gives the exposure for one particular stop, another only for one particular class of subject, and if the exposures have to be calculated for other stops or subjects it is necessary to count a certain number of divisions to the right or left.

These difficulties may be entirely got over by the use of index numbers, and the final exposure calculated in a very simple way by a single addition sum, which may either be performed mentally or jotted down in the exposure note-book.

In the first place, it will be observed that when it is found that any particular exposure is a little too short, the photographer usually doubles the exposure; if it is a little too long the exposure is usually halved. For more accurate work, such as bromide enlarging, where errors of exposure cannot be compensated for by a corresponding increase or decrease of density, it is necessary to make smaller changes by increasing the exposure in the proportion of 3 to 2 or 4 to 3, but the difference between the fractions  $\frac{3}{2}$  or  $\frac{4}{3}$  is not sufficient to make any great difference in the final result, and intermediate intervals are rarely used. It will thus be noticed that doubling and halving are the most important variations commonly made in exposures.

Now, consider the series of index numbers given by the following table:—

TABLE A.												
Number .....	1	2	4	8	16	32	64	128	256	512	1024	
Index .....	0	1	2	3	4	5	6	7	8	9	10	

It will be seen that every time we double a number we add its index, and conversely. Thus, if we add 1 to 2, which is the index of 4, we get 3, which is the index of 8. If we multiply a number by 4 we add 2 to its index, if we multiply by 8 we add 3 to its index, and so on; similarly, to divide by 2, we subtract from the index, and so on.

The mathematician who understands logarithms is perfectly familiar with all this, and we find nothing new in the idea.

For intermediate indices it will be sufficiently correct to take a number midway between the previous and following numbers.  $2\frac{1}{2}$  is midway between 2 and 3, and is the index, roughly speaking, of 6, which is midway between 4 and 8.

If, now, any change in the light value, subject, plate speed, stop requires the exposure to be multiplied by 2, 4, or 8, that requires an addition of 1, 2, or 3, as the case may be, to the index number. All these changes can be taken account of in a single addition sum if we draw up tables of index numbers for the various sun's altitude, weather, stop, subject, and plate speed.

(2) Index of the Sun's Altitude.—The light received from the sun per square foot or square mile of the earth's surface is greatest when the sun is vertically overhead at a place within the tropics at noon. We may take the corresponding index to be 0. When the altitude is 30 deg. the lighting is halved (doubling the exposure so that the index for 30 deg. is 1, similarly for altitude 45 deg. the index is  $\frac{1}{2}$ ).

The following table gives roughly the values of the sun's altitude index for the several intervals preceding and following noon in any country:—

TABLE B.					
January .....	Index.	Interval	July .....	Index.	Interval
February .....	$\frac{1}{2}$	11 to 1	August .....	$\frac{1}{2}$	9 to 1
March .....	1	10 " 2	September .....	1	10 to 2
April .....	$\frac{1}{2}$	10 " 2	October .....	$\frac{1}{2}$	11 to 2
May .....	$\frac{1}{2}$	9 " 3	November .....	2	11 to 2
June .....	$\frac{1}{2}$	9 " 3	December .....	2	11 to 2

For times outside these hours the usual rule would appear to be equivalent to the following:—Add  $\frac{1}{2}$  for every hour till the index number is about 24. This index number corresponds to an altitude of about 10 deg., after which the changes of altitude cause a variation in the index, and the effects of a variation in latitude or an error in estimating the longitude in order to correct the would be considerable.

For this altitude the shadow of a stick is about 5.6 times the height of a stick. If it is required to make use of the last gleams of sunshine in photographing an object which cannot be re-visited, or, indeed, to make use of the strong contrasts obtained when the sun is shining low down in the sky, the best way is to measure the length of the shadow of a stick and divide it by the length of the stick. Thus, if a stick 3 feet long gives a shadow 12 feet long, that is, 4 times the length of the stick, we take the index number under 4 as the altitude index of the sun, and this from Table A is 2. If the length is 12 times the length of the stick, then, since 12 is midway between 8 and 16, we take the index to be  $3\frac{1}{2}$ , and so on. This method only answers at low altitudes, for if the shadow were the same length as the stick, the altitude would be 45 deg. and the index would be  $\frac{1}{2}$ , whereas the index number opposite 1 is 0, and gives an incorrect result.

(3) Weather Index.—If we take the brightest sunshine to have as its index, the index numbers for the states described in the Burroughs, Wellcome, and Co. light tables will, except in the extreme cases when the sun is low down in the sky, be as follows:—

TABLE C.

"Bright Sunshine" .....	0
"Sun Shining through Light Clouds" .....	$\frac{1}{2}$
"Diffused Light" .....	1
"Dull" .....	$1\frac{1}{2}$
"Very Dull" .....	2

The correction for height above sea-level will be made according to the B.W. Tables by subtracting  $\frac{1}{2}$  for 2,500 feet. According to another source the index is  $\frac{1}{2}$  for cloudy and 1 for gloomy weather.

(4) Aperture or Stop Index.—The proper unit to take in this case the maximum aperture conceivable. If the lens were close up to the plate (a condition capable of practical interpretation in the case of microscope objectives) the incident light would form a cone of vertical angle 180 deg. The same is the case in contact printing when a plate in its printing frame is exposed to light from the sky all directions out in the open. We may take the index number the aperture in this case to be zero, and the system of index numbers will thus readily enable comparison to be made between exposures in contact printing and enlarging respectively. The list of index numbers for the various apertures will work out as follows:—

TABLE D.

Stop .....	f/4	f/6	f/8	f/11	f/16	f/22	f/45	f/64
Index .....	6	7	8	9	10	11	12	13

This list is easy to remember if we notice that 8 is the index of f/8, the largest stop used with cheap negatives, and that each succeeding stop of the scale commonly used increases the index by unity.

(5) Index for Colour Screen.—For a 2, 4, or 8 times screen the corresponding index numbers will be 1, 2, 3 respectively (Table A).

(6) Index for Objects in the Shade, Narrow Streets, and Ravines.—In this case the most rational plan, if the sun is not shining directly on the objects, is to make a rough estimate of what proportion of the sky is visible from the point at which the objects to be photographed are situated. For example, if a group is under the shadow of a tall building or perpendicular rock, only one-half of the light from the sky will fall on it, and the corresponding index is 1. The rule will be as follows:—

TABLE E.

Proportion of sky visible ...	$\frac{3}{4}$	$\frac{1}{2}$	$\frac{1}{4}$	$\frac{1}{8}$	$\frac{1}{16}$
Index .....	$\frac{3}{4}$	1	$1\frac{1}{2}$	2	$2\frac{1}{2}$

(7) Index for Interiors.—Here the opening in the windows takes the place of the stop in the camera, and the light admitted to the room correspondingly reduced. If the window is not opposite any tall buildings the index can be calculated by measuring the area of the window in square feet, and the distance of the windows to the opposite wall of the room. In taking indoor portraits the distance should be measured from the sitter to the window. The rule will be as follows:—Double the index of the distance from the window and add  $\frac{1}{3}$  to it, and subtract the index of the area of the windows.

For a skylight receiving light from the sky in all directions the constant to be added would be the index of 3.1416, which is just over  $\pi$ . For a window in a wall only half the sky is visible, making the

constant  $2\frac{1}{2}$  or over. The absorption by the glass of the window would increase the constant, but it would be slightly decreased by the light reflected from the ground. Probably 3 would be safer than  $2\frac{1}{2}$ , except when a very light foreground outside is exposed to strong glare, or there is snow on the ground, when it might be possible to reduce the constant down to 2.

(8) Subject Index.—The subjects which require the shortest exposure are sea and sky, and the natural plan is to take the index of such subjects as zero. We then have the following list:—

TABLE F.

Clouds and sky .....	0 to 1
Sea .....	1
Open landscapes, shipping, etc. ....	2
Landscapes with bright foreground ..	3
Street scenes, groups, landscapes with strong foreground	4
Outdoor portraits in shade .....	6

(9) Index of Plate Speeds.—This has to be so chosen that when the various indices are added up their sum which gives the exposure index is 20 when the exposure is 1 second. This is a matter of convenience, but it is a fortunate coincidence that this makes the speed index zero for the fastest plates on the market working with the most efficient focal plane shutters.

The speed index of the various brands of "Special Rapid" plates with an H and D speed of about 200 is  $2\frac{1}{2}$  for a full exposure or 2 for a short exposure. The plates of half this speed (H and D 100) would have an index  $3\frac{1}{2}$  for a full exposure.

(10) Exposure Index.—As just stated, it is convenient to choose the exposure index, so that for an exposure of 1 second the index is a multiple of 10, and 20 is the smallest multiple that will answer the purpose. The system of indices of the plate speeds just described is based on this choice, but happens, as we have said, to exactly fit the circumstances of the case. With this convention the complete table of exposure indices will stand as follows:—

TABLE G.

Index ...	10	10 $\frac{1}{2}$	11	11 $\frac{1}{2}$	12	12 $\frac{1}{2}$	13	13 $\frac{1}{2}$	14	14 $\frac{1}{2}$
Exposure	$\frac{1}{1000}$	$\frac{1}{800}$	$\frac{1}{640}$	$\frac{1}{512}$	$\frac{1}{400}$	$\frac{1}{320}$	$\frac{1}{256}$	$\frac{1}{200}$	$\frac{1}{160}$	$\frac{1}{128}$
Index ...	15	15 $\frac{1}{2}$	16	16 $\frac{1}{2}$	17	17 $\frac{1}{2}$	18	18 $\frac{1}{2}$	19	19 $\frac{1}{2}$
Exposure	$\frac{1}{80}$	$\frac{1}{64}$	$\frac{1}{50}$	$\frac{1}{40}$	$\frac{1}{32}$	$\frac{1}{25}$	$\frac{1}{20}$	$\frac{1}{16}$	$\frac{1}{12}$	$\frac{1}{10}$
Index ...	20	20 $\frac{1}{2}$	21	21 $\frac{1}{2}$	22	22 $\frac{1}{2}$	23	23 $\frac{1}{2}$	24	24 $\frac{1}{2}$
Exposure	$\frac{1}{10}$	$\frac{1}{8}$	$\frac{1}{6}$	$\frac{1}{5}$	$\frac{1}{4}$	$\frac{1}{3}$	$\frac{1}{2}$	$\frac{1}{1}$	$\frac{1}{1}$	$\frac{1}{1}$
Index ...	25	25 $\frac{1}{2}$	26	26 $\frac{1}{2}$	27	27 $\frac{1}{2}$	28	28 $\frac{1}{2}$	29	29 $\frac{1}{2}$
Exposure	$\frac{1}{40}$	$\frac{1}{32}$	$\frac{1}{25}$	$\frac{1}{20}$	$\frac{1}{16}$	$\frac{1}{12}$	$\frac{1}{10}$	$\frac{1}{8}$	$\frac{1}{6}$	$\frac{1}{5}$

(11) To reduce from seconds to minutes, subtract 6 from the index of the exposure in seconds (6 is easy to remember, being the first figure of 60, the number of seconds in a minute). This is equivalent to dividing by 64, which is quite sufficiently accurate for the purpose of calculating exposures.

(12) Final Rule.—The whole process of calculation may now be summed up in the following single rule:—

Add together the index numbers for the day and hour, weather, subject, plate speed, and stop; the final sum gives the exposure index. In working in interiors the index calculated, as explained in Section 7, must also be added, and if a colour screen is used its index must be also added in.

Examples.—In illustration of the index method we append the following examples:—

Ex. 1.—January, between 2 and 3 p.m., cloudy (diffused light), open landscape, with no strong foreground, special rapid plate, stop f/16.

	Table.	Index.
Sun's altitude up to 1 p.m. ....	B	2
Correction for 2 hours .....		1
Weather .....	C	1
Subject .....	F	2
Plate speed .....		$2\frac{1}{2}$
Stop f/16 .....	D	10

Exposure index 18 $\frac{1}{2}$   
Required exposure= $\frac{1}{4}$  second

Ex. 2.—Landscape with strong foreground, taken near sunset, tripod 4 feet high, casts a shadow 38 feet long, slight haze in sky, special rapid orthochrome plate, with 4 times screen top f/32.

Here the shadow is more than 9 times the height of the tripod, and

will lengthen before the picture is taken; we therefore take the next higher altitude index corresponding to a shadow 12 times height.

	Table.	Index.
Sun's altitude .....	A	$2\frac{1}{2}$
Corrections for haze .....		$\frac{1}{2}$
Subject .....	F	$\frac{1}{2}$
Plate speed .....		$2\frac{1}{2}$
Colour screen .....	A	2
Stop $f/32$ .....		12

Exposure index  $23\frac{1}{2}$   
Required exposure = 11 seconds.

Ex. 3.—February, 3 p.m., "very dull," indoor portrait, sitter distant 6 feet from a window, measuring about 15 square feet in area, facing a building which cuts off about  $\frac{1}{3}$  of the sky, as seen from the window, ordinary plate half the speed of the "Special Rapid," stop  $f/22$ .

	Table.	Index.
Sun's altitude up to 1 p.m. ....	B	$1\frac{1}{2}$
Correction for 2 hours .....		1
Weather .....	C	2
Subject portrait, referred to the open .....	F	6
Correction { Distance from window $2\frac{1}{2}$ for { Constant $2\frac{1}{2}$ Interior. { Area of window $4$ $2 \times 2\frac{1}{2} + 2\frac{1}{2} - 4 =$		$3\frac{1}{2}$
Effect of obstruction $\frac{2}{3}$ light visible .....	E	$3\frac{1}{2}$
Speed of plate .....		11
Stop $f/22$ .....	E	11
Exposure index in seconds .....		29
Reduction to minutes, subtract .....		6
Exposure index in minutes.....		23
Required exposure = 8 minutes.		

(13) Index Tables for Actinometers.—If an actinometer be used its time of exposure will be calculated under the conditions, as to weather, under which the photograph is required, and if used in an interior it will give the light value for that interior. There will thus be only a single index in place of those of §§2, 3, 6, and 7. The rule for calculating the index of the light value from the actinometer time will necessarily vary with the actinometer used. With the Imperial actinometer the index of the light value appears to be obtained by subtracting  $21\frac{1}{2}$  from the index of the exposure in seconds (Table G), or 15 from the index of the actinometer exposure in minutes if the final exposure is to be calculated in seconds.

(14) The advantages of the Index method may be summarised as follows:—

- 1.—The calculation of exposures is reduced to a single addition sum.
- 2.—Slide rules are dispensed with. As we have seen, these do not suffice to take account of all the data required in determining an exposure.
- 3.—Any number of factors on which the exposure depends may be taken into account, and the method is thus applicable under the most complex conditions.
- 4.—Cumbersome fractions are avoided, only halves being used in the index numbers.
- 5.—When the sun is low down in the sky a change of latitude or longitude would cause a considerable error in the light value if calculated from tables, and in this case an estimate based on the length of the shadow can be substituted, which is free from this uncertainty. If it were necessary to use an actinometer the light might go while the paper was blacking up.
- 6.—There would be no difficulty in graduating a camera with the index numbers of the different stops and exposures, and in this way the calculations would be further simplified.
- 7.—There is practically no need to take account of the tens in the addition, as there is no fear of mistaking, for example,  $13\frac{1}{2}$ , or an exposure of  $\frac{1}{75}$  for  $23\frac{1}{2}$ , which gives an exposure of 11 seconds.
- 8.—The rule for conversion from seconds to minutes is very simple and easy to remember.
- 9.—It is not difficult to write down the exposures corresponding to the various indices without looking at the table by counting powers of 2 or  $\frac{1}{2}$  from the nearest multiple of 20. Thus, for example, if the index is  $23\frac{1}{2}$ , or  $3\frac{1}{2}$  more than 20, we count (1, 2); (2, 4);

(3, 8); ( $3\frac{1}{2}$ , 12); or the exposure is 12. If the index is  $17\frac{1}{2}$  short of 20, we count (1,  $\frac{1}{2}$ ); (2,  $\frac{1}{2}$ ); ( $2\frac{1}{2}$ ,  $\frac{1}{2}$ ). In this way anyone can easily employ his own method of counting, which will certainly understand better than following mere printed instructions.

G. H. BRYAN, Sc.D., F.R.S.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between June 1 and 6:—

PLATES.—No. 11,816. Improvements in the method of producing sensitised plates and in means therefor, and for exposing the plates in a camera. Arthur Augustus Brooks, 57, Barton Arcade, Manchester.

CAMERAS.—No. 11,835. Improvements in devices for adjusting focussing slides of cameras. Emil Wünsche Akt.-Ges. für Photographische Industrie, 57, Barton Arcade, Manchester.

PLATES.—No. 11,842. Improved means and apparatus for the treatment of photographic plates, films, and the like. Sidney Herbert Nathan, 115, Cannon Street, London.

CAMERA STAND.—No. 11,901. Improved easel, suitable for use with a photographic camera stand. Edmund Hodgson Smart, 23, Southampton Buildings, London.

CINEMATOGRAPH.—No. 11,968. Improvements in cinematograph apparatus. Arcade Mallet, Birkbeck Bank Chambers, Southampton Buildings, London.

CINEMATOGRAPHS.—No. 12,059. Improvements in processes of apparatus for projecting cinematographic projections. John Mathias Arnold, 111, Hatton Garden, London.

CHEMICALS.—No. 12,071. Improvements relating to the manufacture of ammonium thiosulphate. August Zimmermann, 24, Southampton Buildings, London.

TONING.—No. 12,341. Improvements relating to toning reagent processes for toning photographic prints. Harry Edmund Smith, 322, High Holborn, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

SELF-PORTRAIT SHUTTER RELEASES.—No. 14,728, 1907. The invention consists in a device for effecting the automatic operation of the shutter after a certain determined interval of time, during which the photographer may retire from the camera and thus himself appear in the picture. The release is of pneumatic type, that is, the interval before actuation of the shutter of the camera is determined and regulated by pneumatic means. Gravity is the force serving to actuate the mechanism. A weight is employed in combination with a pneumatic cylinder, together with means for transmitting the pressure of the weight to the trip-mechanism of the shutter and means for automatically attaching the apparatus to the camera. Charles Chase Lee, 32, Lightston Street, San José, California, U.S.A.

PHOTO-PENDANTS.—No. 28,233, 1907. The invention has for its object to provide means whereby pendants may be made in a cheap and effective manner, and to enable a photograph being inscribed expeditiously.

Fig. 1 shows a front and side elevation of a photograph pendant made in accordance with the invention. Fig. 2 is a vertical section of the same, and fig. 3 a side view.

Figs. 4, 5, and 6 are detail parts. *a* represents the photograph frame provided with a double bezel *b* *i*, *e*, one on each side to hold two pictures. The frame is made in the form shown in side view fig. 2, and the end view fig. 4.

A fork-like carrier *d* is made as shown in side view (fig. 5), and

lan (fig. 6). This carrier consists of two prongs *e, e*, adapted to take and hold two pictures back to back within the groove.

When the pictures are in their place the carrier *d* is placed in the frame *a*, the spring *g* (fig. 2) clips and tightens up the prongs

Fig. 1.

Fig. 2.

Fig. 3.

*e*, against the edges of the pictures, on pressing the holder down into the position shown at fig. 1.

In some cases a notch is formed at *h, h*, with which the ends *i, i* of the spring *g* engage. The object of this is to afford a better hold when the carrier *d* is in its place in the frame.

On pressing the prongs *e, e*, laterally the carrier is easily

Fig. 5.

Fig. 4.

Fig. 6.

inserted in the frame. The carrier *d* is furnished with the ornamental attachment *j* for the purpose of attaching the same to a watch-chain or the like. Instead of making the spring *g* in the manner shown at fig. 2, a short spring may be attached to each side of the frame *a* so arranged as to press laterally against the prongs *e, e* for the purpose of contracting the same. Clarence Flint, 186, Park Road, Bearwood, Birmingham.

**FAST LOADING OF PLATES.**—No. 4,338. 1908. The invention consists in means of packing plates in readiness for exposure in a camera without the aid of dark-room or changing bag. Two plates are arranged back to back with an opaque backing sheet between them. Against each film surface two frames or strips are so arranged as to form frames a sufficient distance apart to admit of a slide or shutter passing between them.

The materials preferably employed are cardboard and paper, or other inexpensive light materials, while a suitable fabric may be employed for binding the parts together, and in this manner the plates are packed in pairs in what practically amounts to a double slide of such a construction and produced at such a cost as to admit of its being destroyed after the plates have been used. In practice it is preferred to pack six of these frames, each containing two plates, in a box, the frames being taken direct from the box and inserted in the camera. Guy Arthur Chambers, Reponga, Gisborne, New Zealand.

**ATTACHMENT.**—No. 21,470. 1907. The invention relates to a photographic posing chair, having adjustable head and arm rests. The primary object is the production of a device of this character which can be applied to any type of chair or stool and be adjusted to hold a child in the desired pose for taking its picture. By varying the direction and form of the holding arms it may be used vertically, horizontally, or at any angle, as may be most convenient in securing it to an object. The support may serve

as a back-rest, and the entire device will be hidden from the point of view from which the picture is to be taken, and to otherwise improve on devices for a similar purpose. The details of the construction of the chair require the six drawings in the specification for their explanation. Frederick William Charles Pohle, 380, Plymouth Avenue, Buffalo, New York State, U.S.A.; and Paul Werner, 330, Hudson Street, Buffalo.

**CINEMATOGRAPHS.**—No. 22,109. 1907. The invention relates to a cinematographic apparatus of the kind known as the start-and-stop type, that is, of the kind in which the feeding of the film is intermittently effected through the medium of a Maltese cross and eccentric pin feeding-drum.

The invention has for its object to provide improved means whereby the position of the film with respect to the optical axis of the lens can be adjusted.

The feed spindle upon which the Maltese cross is mounted is made hollow, and is provided with a longitudinal slot. Upon this spindle there is loosely mounted a sleeve carrying the usual pair of toothed feed wheels, around which the film passes. This sleeve is formed with a spiral slot or internal recess. Extending through the hollow spindle is a rod, the outer end of which projects beyond the end of the spindle. The inner end is provided with a pin or projection, which extends through the slot in the spindle, and engages with the spiral groove or recess in the sleeve.

With this arrangement by moving the rod axially within the hollow spindle the sleeve is caused to partially rotate, thus adjusting the film relatively with the optical axis of the lens without in any way interfering with the relative position of the other parts of the apparatus.

In practice it is advantageous to form the hollow spindle with two longitudinal slots opposite one another, and to make the rod which extends through the spindle with two pins or projections at its extremities, which pins engage the slots. Moreover, the spiral slot or recess in the feed drum sleeve is preferably so made that the normal feed movement of the sleeve tends, with the assistance of a spring, to force the adjusting rod outwards, so that the requisite adjustment of the film at any time can be easily effected by the operator, who merely has to press the rod more or less inwards. The rod may be retained in the position to which it is adjusted by any suitable means. Alfred Wrench, 50, Gray's Inn Road, London; and William Engelke, 72, Duke's Avenue, Muswell Hill, Middlesex.

The following complete specifications, etc., are open to inspection before acceptance under the Patents Act, 1901:—

**CINEMATOGRAPHS.**—No. 11,968. Cinematographic apparatuses Mallet.

**CINEMATOGRAPHS.**—No. 12,059. Process of, and apparatus for, projecting cinematographic projections. Arnold.

## New Trade Names.

**MATONE.**—No. 301,113. Chemical substances used in manufactures of photography, or philosophical research and anti-corrosives. Lewis Berger and Sons, Ltd., 201, Morning Lane, Homerton. London, N.E., manufacturers. March 7, 1908.

## CONVENTION LYRICS.—No. 5.

At Antwerp, that town by the Scheldt,  
Some slight curiosity's felt

Lest the members should try,

On the 10th of July,

To pronounce all French words as they're spelt.

**THE BLENHEIM CLUB**, which on Monday last installed itself in new quarters, formerly known as Willis's Rooms, took fire just as the first lunch of its career was being laid. The fire originated in the kitchens on the top floor, and within a few minutes the greater part of the roof was a mass of flame, the spectacle attracting a huge crowd. A district call was given, and occupants of surrounding property began hastily to remove their belongings. With the prompt arrival of a large force of firemen, however, the danger was quickly at an end, and after an exciting twenty minutes the fire was extinguished.

## Analecta.

### Caravanning for Photographers.

As many will be quite at sea (states a writer in "The Amateur Photographer and Photographic News" for June 16) as to the probable cost of this type of holiday, I append a few figures. A van for two persons costs, to-hire, in August, the sum of fifteen guineas; in July and September ten. The vans are not let for less than one month at a time. The hire of the horse is £1 per week, and 2s. 6d. per week extra is charged for insuring it—a very desirable precaution. A coachman, who may be taken or not, as fancy dictates, costs 25s. per week. Food for the party costs as much or as little as you choose to pay. The horse's food and stabling, in my own experience, works out at 2s. 6d. per day. For a photographic tour, caravanning is ideal. The moment you have "worked out" a neighbourhood you move on to another—taking your "lodgings" with you. Not that one really works out any neighbourhood; but undoubtedly one gets "stale" if a whole month of the summer be spent in one place, however beautiful. I never developed any plates in the caravan, but I changed them every night, making a dark-room by pulling the curtains across one of the bunks and working within. I have changed plates during the day, similarly; but this takes more preparation. Development would be quite feasible at night—as long as the other members of the party do not mind being inconvenienced. Frankly, there is not much elbow-room in a caravan!

## New Books.

"Annuaire des Photographes Professionnels pour 1908." (Second Edition.) Paris: Office of the "Photo-Revue." 1fr. 50c.

This publication is a new edition of a directory of professional photographers in France, the French colonies, and Belgium and Switzerland. Photographers in Paris are listed separately from those in the "départements," and the list is certainly a useful one for reference. To what extent the value of the list is nullified by the migratory habits of photographers it is not possible for us to say, but we fear a similar list of photographic studios in Great Britain would—within a twelvemonth—become so inaccurate as to be commercially of very little value.

"Répertoire Général des Marques et Spécialités Photographiques et Cinématographiques." Paris: Office of the "Photo-Revue." 3fr. 50c.

This most useful compilation is a directory of trade names of photographic articles of manufacture (apparatus and materials). The entries are arranged in alphabetical order, and against each are given details as to the nature of the article and the name of the manufacturer, thus:—Cristallos—developers and fixers, intensifiers, etc. E. Jumeau, Paris.

The list is not confined to articles of French manufacture, but appears to include the trade names of Great Britain, America, and Germany. It is certainly most useful, despite the fact that the compilers appear to have relied on French sources alone to collecting their data. For example, under "Ensign," they give only the name of "The Austin Edwards Company, London," and ignore the many articles manufactured by Messrs. Houghtons Ltd. under this trade mark. The directory also includes a list of trade marks which have been abandoned or are thought to be so, the articles to which they refer being no longer manufactured.

Incomplete as such lists are bound to be, the present publication is certainly a most useful one, and should be worth its cost many times over to the dealer or wholesaler, who is asked to procure some article of which he has never heard.

"THE BLUE BOOK," 1908.—This pocket-book of the Scottish Photographic Federation apparently bases its claim for approval chiefly on being a complete photographic guide to Scotland. The "Gazetteer" section of the "Blue Book" is the largest, yet we doubt whether any one would seriously set out on a photographic

tour of Scotland under its guidance. Our own opinion is that the guide-book work that is being done by the Scottish Federation and other similar bodies is most of it sheer waste of time. It ignores the personal equation. The scenery that a guide-book may describe as "fine and picturesque" will fail to please one man, while another may think it a photographer's paradise. For example, our "Blue Book" tells us that at Pollokshaws there is "the Pollok Estate, River, Calt, Crookston Castle and woods (apply Factor, 216, George Street, Glasgow)." Seriously, one asks whether a federation that wants to do something is wise to let its energies lead it in this direction. But, indeed, we must do the Scottish Photographic Federation the justice of saying that in many instances it has appointed "reporter," who presumably is able and willing to intending visitors information they need. The "Blue Book," contains a directory of a goodly array of Scots prepared to help photographic (and federated) brethren in some branch or other practical work. There is also the circulating portfolio of the federation.

"CAMERA WORK." No 23.—The current issue of this engaging magazine is, as far as its illustrations are concerned, a Clarence White number. There are sixteen sumptuous plates, all instinct with high artistic feeling and originality of idea. We ourselves place a feeling above their originality, for the groping after a new and hackneyed method of attack does not always result, happily for the artist. Mr. White seems deliberately to traverse many of the principles accepted by painters and photographers alike. For example in the portrait of Miss Everett he has introduced disquieting lights upon what is presumably a muff. If the hand is placed in this plague spot to hide it the rest of the work is extremely beautiful. Similarly the bright spots made by the hand and the flower in "Girl with Rose"—a sort of echo of Rossetti's "Blessed Damsel"—throw the chief appeal of the picture into its secondary parts. The lighting of this is quite unexplained. Mr. White is fond of forcing out a spot of dazzling brilliance and leaving the rest of the picture in an illogical gloom. The plan may add force, of a sort, but certainly adds no beauty. To our minds the best of these pictures are two highly romantic works, "Morning" and "Boys Wrestling," which pleasantly posed "Mr. Harrington Mann." But all are remarkable in some way or other. A note upon Mr. White's work is given by Chas. H. Caffin, and Mr. Steichen contributes an article on painting and photography, wherein he says anew many things which have been said often enough before. His sincerity and conviction, style, however, give his article freshness and much interest. Alfred Stieglitz treats of the frilling of Autochromes.

## New Apparatus, &c.

The Busch "Leukar" Anastigmat. Sold by the Emil Busch Optical Company, 35, Charles Street, Hatton Garden, E.C.

This is a symmetrical double anastigmat of  $f/6.8$  aperture, and very small and compact form. The No. 2, which is between 4 and 5½ inches in focus, will cover anything up to 7 x 5. Thus, as it is listed to cover a 4-plate sharply at full aperture, we find it gives very good results on a half-plate. The complete doublet is an excellent lens for general work, and the price, £3 15s. for the No. 2, is certainly moderate. The corrections seem to be very good, the single combination also serves well as a narrow angle long focus objective. "Leukar" lenses can be obtained in three varieties of mount—a plain iris mount, a focussing mount, and a "bellows" mount, with which the flange comes at the front of the lens. Focal lengths vary from 2½ to 18 inches, so there is a wide range to select from. "Leukars" are also supplied in Unicum, Automatic, Koilos shutters, and a No. 2, in Koilos shutter, only costs £5 10s.

SUICIDE OF AN EX-PHOTOGRAPHER.—At Darlington last week the verdict of "Suicide whilst temporarily insane" was passed upon Tobias R. Braybrook, formerly a photographer in Church Street, West Hartlepool. At the time of his death deceased was a well-known traveller.

## New Materials, &c.

ette" semi-matt P.O.P. Made by the Halifax Photographic Company, Halifax.

Is brand of P.O.P. the half-matt surface of albumenised paper many collodion P.O.P.'s is very successfully obtained. The tints and tones well in the ordinary sulphocyanide bath, and ults obtained with it are very effective for portrait work, giving prints particularly suitable for reproduction. The new obtainable in the usual sizes of packets and as postcards.

ORNE" AND "REMBRANDT" MOUNTS.—Mr. H. W. Green, of Wm. Manufactory, Rotherham, sends us specimens of a new f mount, the "Osborne," which is supplied, with embossed ark, in white, green, or brown. The mounts are put up in 1,000 packets, and are made for circle, oval, and rectangular. Prices are moderate, 3s. 3d. per 100 for 9 x 6½ mount, for cabinet or 4in. circle, or 30s. per 1,000.

Rembrandt" is a mount with a pasted-on ornamental tint, old at 4s. 11d. per 100 in 9 x 6½ size, or of slip-in pattern cards or cabinets at 6s. 6d. per 100.

## CATALOGUES AND TRADE NOTICES.

STOCK LENSES.—A most handsomely printed list, containing is half-tone reproductions, is this of the Munich firm of Roden-foreover, the tables and rules given in the first twenty pages contain a good deal of information of a kind which is of service in the choice and use of a photographic lens. The rt of the list gives very full specifications of the lenses and made by Rodenstock, and obtainable, as is the catalogue om the British agents, Chas. Zimmermann and Co., 9 and 10, y-at-Hill, London, E.C. Special mention should be made two pieces of accessory apparatus, such as the iris universal ler and a screen-holder by which circular iso screens of izes can be quickly attached to lenses, also of various sizes.

NGTON and Co., of Sydney and Brisbane, Australia, send price list of photographic goods for 1908-9. It is a sub-volume of 360 pages, and shows the very full representation ritish and Continental goods of the leading makers obtain in Harrington's hands among photographers in the Antipodes.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JUNE 20.

Amateur Photographic Association. Excursion to Blackburn and Essex Photographic Society. Record Outing to Pinner. Era Club. Excursion to Otley. Urban Photographic Society. "London and the River." F. J. er, F.R.P.S. eoscopic Society. Outing to Zoological Gardens. Riley Fortune. Photo Art Club. Excursion to Midmar.

TUESDAY, JUNE 23.

otographic Society. "Hand Cameras."

WEDNESDAY, JUNE 24.

otographic Society. Excursion to Grandborough. G. B. Morgan. Essex Photographic Society. Exhibition of Affiliation 1907 Prints.

THURSDAY, JUNE 25.

Provincial Photographic Association. Annual General Meeting. Photographic Society. "Hyposulphite of Soda, its Chemical and ropic Properties." C. F. Proctor.

### ROYAL PHOTOGRAPHIC SOCIETY.

held Tuesday, June 16, the president, Mr. J. C. S. Mum- the chair.

eting was the occasion of the opening of a house exhibition raphs by Mr. Walter Benington, who, in the shortest of ry addresses, said that all he had to say in reference to raphs was on the walls.

Jules Richard and Co. exhibited a number of stereoscopes

of their taxiphot reservoir pattern, containing Autochrome stereo- scopic transparencies. These will be on the tables during the hours at which the Benington exhibition is on view—namely, daily from 11 to 5. A paper was then read by Mr. Horace Mummery on "The Artistic Impulse," which called forth some interesting discussion.

## Commercial & Legal Intelligence.

A NORFOLK BANKRUPTCY.—The creditors of Scott Stanley Meale, photographer, of Coltishall, Norfolk, met at the Official Receiver's office, Norwich, on June 10. Debtor returned his liabilities at £580 12s. 2d., and assets at £503 12s., leaving a deficiency of £77 0s. 2d. The Official Receiver said the receiving order was made on the debtor's own petition, consequent upon three creditors having obtained judgments against him. Debtor had been a photographer at Coltishall since 1896. In April, 1907, he acquired the premises in which he had been carrying on business for £420, raising the greater part of the money upon mortgage. Latterly he had found himself hampered for want of money, but he regarded himself as solvent, believing the premises to be worth what he gave for them. When he tried to sell them, however, he was unable to find a purchaser. The principal creditors are the mortgagees of the property and the debtor's bankers, who hold a policy upon his life. Debtor attributes his insolvency to bad trade. The Official Receiver remains trustee of the estate.

LEGAL NOTICE.—A dividend is to be paid in the bankrupt estate of Arthur Frederick Eastmead, photographer, of 173, High Street, Rochester, Kent. Proofs should reach the Official Receiver at Maidstone by June 26.

THE INSTALMENT BUSINESS.—At the Ashby-de-la-Zouch County Court last week, before his Honour, Judge Wrightman Wood, Esther Wright, wife of John William Wright, collier, of Spring Cottage, Overseal, Leicester, sued A. and G. Taylor, photographers, of Queen Street, London, E.C., for £1 7s., money paid by the plaintiff to defendants. There was a similar action by plaintiff's husband, John William Wright, against defendants for 32s. Mr. A. H. Timms appeared for the plaintiffs, and Mr. Lister, confidential clerk to the defendant's firm, appeared.

Mr. Timms said in this case the order for the photographs was given in March, 1901, the photographic firm being then at Derby.

John William Wright stated that he gave the order for his photograph in 1901 to a man named J. J. Askew. He received a card and paid a deposit of 1s. upon it. He continued to pay instalments regularly for about three months. Twelve months after the calls ceased he wrote to the defendants at Derby.

His Honour remarked that the last stamp, which formed the receipt, was dated November, 1903.

Mr. Lister said his firm never received the letter referred to. The only letter they received was in last August, in which Mr. and Mrs. Wright said that after four years they had changed their minds, and asked for the money paid on account, £2 19s., should be refunded.

His Honour asked what they could get for all that money. If they came to Ashby they could get their photographs taken for 5s.

Mr. Timms: Of course they could.

In reply to his Honour, Wright said that for 45s. he was to have an oil painting and half a dozen cabinets.

His Honour, after examining the letter produced by Mr. Lister, said that the date was evidently January, 1908.

Wright said that for a short time after the agent ceased to call he went to Derby to have his sitting, and found 65, London Road, but not A. and G. Taylor. He discovered the London address from a case reported in the "Burton Chronicle," and which took place in the Burton County Court. After receiving a letter from a firm stated to be the liquidators of the Derby and District Photographic and General Supply Company, of 24, The Strand, Derby, he placed the matter in the hands of his solicitors. In further correspondence the defendant company laid the blame on the plaintiff, and stated that they were prepared to carry out their part of the contract, and, further, that that part of the business had been sold three or four years, and had since been placed in liquidation.

Mr. Lister stated that his firm were prepared to carry out their

part of the contract, and gave the plaintiff opportunity of having a sitting at Overseal, but he failed to have it.

Wright said he had only one opportunity. He denied that the agent ceased to call at his request.

Mrs. Esther Wright said someone called at her door in March, 1901, and showed a specimen portrait. She gave an order, and the collector called once a week for three or four months. He then got very irregular, and finally four years ago ceased to call at all. When they were given an opportunity of sitting it was not convenient as they had not paid in sufficient. She went to Derby with her husband, and found that the shop at 63, London Road, was closed.

Mr. J. J. Askew, of Hanley, for the defence, stated that he managed the Derby business up to four years ago, and took the order from the plaintiffs. Mr. Lamb then took over the management, and after eighteen months or two years the business was sold to the Derby and District Photographic and General Supply Company.

Mr. Lister again said that Mr. Taylor was prepared to fulfil his part of the contract, and had given every opportunity for sittings.

His Honour said he could not accept that view. He thought defendants had broken the contract in two ways. It was clear that the collector should have called from time to time, and this he failed to do, and then the defendants had changed their address without notifying the plaintiffs. He thought that was a most unscrupulous thing to do. He did not think the plaintiffs were bound to have their photographs taken until they had paid all the money. He did not know, but the woman might be vain enough to hold that, whilst she was prepared to have her photograph taken in 1901, she might not desire to hand down to posterity her photograph as she was in 1908. He should give judgment for the plaintiffs in both cases, with costs.

## Correspondence.

\*• *We do not undertake responsibility for the opinions expressed by our correspondents.*

\*• *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### A NOVEL METHOD OF PHOTOGRAPHING INTERIORS.

To the Editors.

Gentlemen,—In these days of great photographic possibilities one is often obliged to take in a great deal connected with what used to be called our "art-science," but it is not often one is expected to actually swallow a camera and electric light plant at one gulp. The following paragraph is from "Tit-Bits," June 15:—

"PHOTOGRAPHING THE STOMACH.—An improved apparatus has been made by Dr. Fritz Lang, of Munich, by which the inside of the stomach can be clearly photographed. The camera is actually swallowed by the patient, and no sooner does it reach his stomach than the walls thereof are illuminated by a small electric lamp attached to the apparatus. At the bottom of the camera is wound a photographic film 20in. long and a quarter of an inch wide. All the surgeon has to do is to pull the cord and thus run the film past the lens. The electric light is then turned on, and after the sensitive film has been impressed with the image the current is turned off and another section of the film is brought into play until the requisite number of pictures have been obtained. When this is done the entire apparatus is withdrawn from the stomach."

I have written to the gentleman, whose name and address are given, asking if he can make it convenient to come to Brussels on the evening of the Convention conversazione and exhibit the apparatus. If he accepts the invitation we shall doubtless have quite a rush of members anxious to obtain a reliable record of the working of their digestive organs.—Yours truly,

F. A. BRIDGE.

East Lodge, Dalston Lane, London, N.E.

### INK IMPRESSIONS ON P.O.P.

To the Editors.

Gentlemen,—I enclose herewith a piece of Marion's P.O.P., which had been put by in Smiles's "Self-Help." On picking up the book

the piece of paper fell out, and I at once was struck with the print that had come out on the P.O.P. Is it the iron in printers' ink that had decomposed the silver? If not, can you, through your valuable paper, give a solution of the above? I have not toned or fixed paper for fear of losing the characters.—I remain, yours truly,

3, Dixon Terrace, Darlington.

DOUGLAS H. VET

[The effect described by our correspondent is a curious one. Paper is discoloured similarly to stale P.O.P., while the print shows practically no discoloration. That is, the effect is one of printing on a darker ground. On fixing a small portion of the general discoloration disappears, and the printing is then visible in the form of dark lettering on a light ground. The is thus reversed by the fixing operation. A developer darkens lettering in the unfixed print; but has no apparent effect on the print. Lettering is visible on both sides of the paper, and impression on the back takes the form of white lettering on a stained ground when a developer is applied. The impression on back of the P.O.P. is therefore in all probability simply a g impression from the printing ink. That on the front is probably due to an emanation from the ink that renders the silver developable, but at the same time checks any discoloration.—"B.J."]

### THE P.P.A. AND ASSISTANCE TO NON-MEMBERS.

To the Editors.

Gentlemen,—I am directed by the Committee of the Professional Photographers' Association to request the opportunity to announce that in future, when an applicant for admission to membership for immediate assistance in legal or other difficulties, they will consider themselves bound to render the aid required unless applicant joins the Association for at least three years before paying his subscriptions in advance.

The necessity for this resolution arises from the fact that number of applications for admission under the conditions referred to is steadily increasing, showing that while the objects and usefulness of the Association are perfectly well known and appreciated by photographers throughout the country, in many cases it is seeness or other unworthy considerations that prevent them from joining the Association, the funds of which are used to a very extent for the benefit of professional photography generally, personal necessity drives them into the fold. The new regulation is in no sense a hardship. The 15s. for three years' membership would go a very little way if a solicitor were consulted, and in legal matters are involved a solicitor or the Association are generally the only alternatives. But membership includes many other advantages besides legal advice and assistance, and when the cost of membership, which works out at a little over a penny a week is considered, it is obvious that a photographer who has any business at all can hardly fail to find some feature of the Association's that justifies the outlay.—I am, etc.,

ALEXANDER MACKIE, Hon. Secretary.

CELLULOID MANUFACTURE.—The Mitsui concern in Japan (referred to as the "Chemist and Druggist") is about to establish a celluloid factory with a capital of a million dollars, although at present only \$350,000 is needed. The demand for celluloid has increased within the few years, the imports amounting to about \$500,000 annually. Hitherto there have only been two small celluloid factories in Japan. The company intends to produce artificial silk and other celluloid products.

TOURIST GUIDE TO THE CONTINENT.—Not the least valuable of many guide books at the disposal of the tourist is that issued by the Great Eastern Railway Company, and edited by Mr. F. Lindley. The tourist who desires to explore the most picturesque portions of Holland, Belgium, Germany, Switzerland, Austria, Scandinavia will here find, in addition to copious topographical details, the various routes well mapped out, whilst many of the illustrations are of sufficiently large size to give a fair idea of the subjects dealt with. Several good maps also add to the value of the book, which may be obtained from the Continental Department, Liverpool Street Station; 30, Fleet Street, E.C.; and 12a, Roper Street, W.

## Answers to Correspondents.

matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. No unmounted copies of each photograph must be sent with the

### PHOTOGRAPHS REGISTERED:—

Edinburgh, 1, Hanover Street, Edinburgh. Two Photographs. Group of Ten in the Fife and Forth, One with Two Agents.  
"Woodview," Beeston, Leeds. Photograph of Councillor F. Ogden, a Candidate for Parliamentary Division of Pudsey.  
Glasgow, 8, Battle Place, Glasgow. Photograph. Lampden Park Scottish Cup 1902.

SUBSCRIBER.—We should limit the competition to contact prints enlargements. Your division into classes is very convenient, in regard to other rules we do not see that we can say anything except that the cleanness and neatness of the printing mounting, in short, the technical excellence of the work, is the standard that need be considered.

QUESTIONS.—I want to get full particulars (with drawings if possible) of the periscopes used in the submarines of the Royal Navy. You kindly refer me to any published accounts of them or to the required information?—T. C. CHAPLIN.

QUESTIONS.—I cannot answer your question. Matters of this kind are not to be published in detail, as they are kept secret as long as possible, or until a better device is found. The only published descriptions we know of are extremely vague and relate only to tube instruments. The general principle is that of a tube reflector at both ends, the one at the upper end reflecting an image downwards that is observed in the lower reflector. Total internal reflection and also parabolic reflectors have been used, but I believe they have all proved unsatisfactory. What device is in use now we do not know. The Patent Office is the only place where you would be likely to get any information, and that would involve searching the patent specifications.

DAMAGED CARBON PICTURE.—Having received a carbon enlargement of a picture, I find it all covered with what looks like mildew. On trying I am informed that the picture was hung over the fireplace where there could be no possibility of damp to cause mildew.

On rubbing over with a tuft of cotton wool the fungus was removed, but there remain rusty-like marks, varying in size from the head of a pin to the diameter of a pea. It seems to me that they are caused by the mountant that has been used to fix the flexible to the card (on which it is mounted) decaying, or it may be due to impurities in the mount or mountant. Any information as to how these spots could be removed would greatly oblige.—GEO. HAN.

QUESTIONS.—Without seeing the picture it is impossible to say decidedly the nature of the markings. But from the description we have little doubt that they arise from mildew. Probably the picture was damaged when it was first hung over the fireplace, and the mildew developed the mildew. The only suggestion we can make is that the markings be rubbed off with a soft rag and then repainted with water colour.

PAINTING.—(1) I shall feel greatly obliged if you will kindly inform me, through the medium of the "B.J.J." which is the best way to copy a large painting in oils, somewhat dark, in vivid colours, figures of soldiers and horses in the distance, what kind of backing, backed or not, and exposure of same in a studio (well lighted, north light). I have tried ordinary Ilford and backed Ilford, but not satisfactory, although I tried it indoors and out

of doors, clear day, no sun; also one with vivid colours on. (2) During the cold weather and damp I had some trouble with my plates owing to leaving the P.O.P. on the negative over-night, and found in the morning the same stuck, and leaving spots all over the plate. Is there any means to remove such spots from negative?—R. J. OWEN.

(1) As you do not say in what way the result was "not satisfactory" we can only conjecture that you did not use a light filter. Ilford chromatic (preferably backed), with the suitable (Ilford) screen, ought to give you good rendering of the detail in all parts with, at the same time, correct colour values. But the exposure must be ample. (2) Try rubbing over the surface of the negative with pumice powder, afterwards immersing negative in strong hypo solution. If this fails to remove the stains the formula on page 793 of the "Almanac" is about the best remedy.

POSTCARD PHOTOGRAPHS.—A firm of postcard publishers have reproduced three of our photographs as postcards and put them on the market. We have since copyrighted these three. Will you inform us if we can stop them putting any more on the market?—SUSSEX YOKEL (Hastings).

Certainly; you can obtain an injunction to stop further copies, but a letter from your solicitors should be sufficient.

A DISPUTE.—W agrees to take photographs of machines made by the firm of X, and supply a copy for a certain price, the negative to be the property of X, but to remain in the possession of W till X wants it. Y buys the business of W, but he enters into no agreement with W or X concerning the agreement of W with X, either verbal or written. Y takes three or four pieces of machinery and supplies prints in the usual way to X. X's firm bankrupts and pays 10s. in the £. A new firm is established to carry on the same kind of business with some old hands and some new at the head of affairs. X sends for a copy from a negative which Y has lost or broken, so he cannot find it, and tells X so. X wants all the negatives back that W took, as well as those Y took. Can X demand them, considering it is a new firm and Y never signed any agreement whatever?—X Y Z.

It seems pretty clear that, according to the arrangement made, the negatives were the actual property of X, and on the bankruptcy they became the property of the trustee in the bankruptcy proceedings. It is more than probable that they passed, by sale, with all the other estate, to the new firm, and are, in fact, their property. They being the property of X the firm had no right to part with them to Y or anyone else. We expect that Y will have to give them up, as they seem to be the firm's property. But before doing so he might refer the firm to W, as it was he who held the negatives in trust, and should be responsible for them.

S. PORTER.—A light-filter will help matters, reducing glare. Probably also you have too strong front light on the painting. Try a light more from one side.

DAMAGED DAGUERRETYPE.—I should be obliged to you if you could tell me what to use to brighten the enclosed miniature, as it has got rather dull with age. Awaiting your kind reply.—HUTLY SCROFIELD.

The picture has been damaged by someone, who, not knowing the nature of the Daguerreotype image, has attempted to clean off the varnish by rubbing it, and in that way has removed a portion of the image and scratched the plate. The varnish remaining on the margins of the plate may be removed by the method described on page 311 of our issue of April 17 last, but that will not improve the face or the figure.

R. J. P. H.—We are sorry we cannot trace your second inquiry. Please repeat it. "Lustralene" rubbed into the prints may remove grain to some extent, but we doubt if it will be of very great advantage, and its alteration of the appearance of the print may be a drawback if the print is not yours to do what you like with.

ANOTHER DAMAGED DAGUERRETYPE.—Can you tell me if it is possible to restore this Daguerreotype and remove the stains from the face and neck? I should be very much obliged if you will do so.—AMY CASSELS.

The reply given to H. Schofield in this column answers your query. But in your case the stains can be removed to a great extent by the treatment to which we referred that correspondent. You must, however, bear in mind that the Daguerreotype image is a very delicate one to deal with. If the picture is a valued one

we should advise you to put it in the hands of one who is familiar with the working of the Daguerreotype process rather than attempt the work yourself.

**BLINDS QUERY.**—Will you kindly advise me as to the most suitable blinds for my studio, also the colours? I thought of having green and white ones, and is it better to have blinds to fall down or run horizontal, and shall I have three large blinds or six small ones (half the length)? I am trying to obtain a soft lighting on sitters. My studio is very narrow, and the light pours in very strong in summer. Your advice on the matter I shall value. I send measurements of glass in studio. Owing to it once having been an attic there are some very awkward beams which I cannot remove to alter glass.—**STUDIO.**

As the studio is small and there are beams that may interfere with the light we should advise that the blinds run horizontally. In the circumstances you will do better to have six small than three large ones. Although you send a sketch you do not mention the aspect of the building, so that we cannot say definitely what would be the best colour; but green and white, as a rule, are good for most aspects.

**PHOTOGRAPHS ON METAL.**—I have been trying to get a carbon print on to a metal cigarette case, following your instructions in February 7 issue. In my first attempt I succeeded in transferring the picture to case (double transfer), but a few minutes after stripping off the temporary support a split appeared right across the picture, and then it gradually cockled up everywhere and came right off. I tried again, and this time, within five minutes of contact, the support and picture came right away, with a nice glaze, as the gelatine had simply come away with it. Can you kindly explain? Do you think single transfer would be easier, though double transfer seems to me to be the best, as with single transfer one cannot be certain of getting the picture in exact position required? I may say I cleaned the case thoroughly with strong soda water before applying gelatine.—**E. E. CLEEVE.**

It is a little difficult to say the precise cause of your failure. The only suggestion we can make is that the metal was not absolutely clean. It is imperative that it should be so, more particularly in the case of highly polished surfaces. Try cleaning the metal with ammonia and well rinsing afterwards. We think the cause of the trouble lies here, and that idea is strengthened by the fact that the gelatine itself splits off the metal. In producing carbon pictures on metal surfaces it is desirable to have the carbon film as thin as possible, such as one gets by employing a thin negative to print from, so as to obtain an image with very little relief. Thick films of gelatine on a rigid support are liable to contract and split up when they become excessively dry. If you do not get on with double transfer, try single; it is rather easier to work.

**RETURN OF MONEY.**—I have had the misfortune to smash and fog about twelve negatives of people who live in my district, and I have written to all these people asking them to come and be taken over again. Is this sufficient, or ought I to return them their money? I do not wish to return any money, as they all live within easy distance of my studio. What I want to know is, am I compelled by law to return their money if they do not come to sit again?—**ANXIOUS.**

If the people cannot, or will not, come to you and sit again, of course you must return the money they have paid to you. It is not their fault that you accidentally smashed or fogged the negatives.

**E. P. C. (Nailsworth).**—If the prints at once obtained a thorough fixing in plain hypo solution or in one of proper composition they should not suffer.

**PHOTOGRAPHING SILVER PLATE.**—We have arranged to photograph a large silver challenge cup next week, and shall be glad of any hints you may give us on the best way of doing the work. We know that the usual method is to dull the silver by dabbing it over with putty, but this is not allowed by those in charge of the cup. It must not be tampered with in any way.—**J. AND CO.**

The best procedure, under the present circumstances, is this. Place the cup in position and arrange the light so as to have no strong reflections on it. Focus, and get everything ready for the exposure. Then mark the exact position of the cup so that it can accurately be replaced. Next put it in a cold place—out of doors

in cold weather will do, or a cold cellar—so that the metal is thoroughly cold. Then bring it into the warm studio and it in its former position, when in a few seconds moisture will be condensed upon it and dull the surface. The plate should at once be exposed. After the exposure has been made the moisture will quickly evaporate and the metal left as before. I may emphasise the fact that the plate must be exposed immediately the surface of the cup is dulled, otherwise the moisture will continue condensing upon it, and will then trickle down the sides, which would, of course, show in the picture. In a cold weather the same end would be secured by putting a few pieces of ice in the cup.

**COST OF STUDIO.**—Can you tell me the probable cost of erecting a studio for professional work on the top of a house? The space I propose to put up will be 25 x 11 feet. It will have to be substantially built, as it will be much exposed to weather. The roof I propose will be of the ridge-roof form and glazed both sides. What I want to know is how much the building is likely to cost. Any information you can give me in this direction I shall be thankful for.—**AT PRESENT AN AMATEUR.**

Your query is one that it is impossible to answer. Sometimes when a studio is erected on a housetop the alterations necessary to the roof for its reception, the staircase up to it, and incidental expenses come to as much, and in some instances more, than the actual cost of the studio itself. The best advice I can give you is to get out plans of what you want and then show them to a local builder, who, after seeing the premises, will give you an estimate for the work.

THE "FINANCIAL NEWS" HOLIDAY NUMBER, which was published with the ordinary daily issue of that paper on Monday last, is a gazetteer in brief and concise form for the help and information of the tourist, whether at home and abroad. The matters dealt with are of a practical character, including such necessary details as routes by which to travel, cost of tickets, hotels, boarding-houses, etc., whilst two good maps, one of Great Britain, the other of Central Europe, add to the efficiency of the publication.

**A NEW KODAK COMPETITION FOR EASTMAN PLATES.**—A competition, in which handsome cash prizes amounting to £240 are offered, is announced by Kodak, Ltd. The competition is for amateurs done upon Eastman plates, and is divided into three classes: Class I., for novices, restricted to those who have never won a prize in a photographic competition; Class II., open for amateurs not competing in Class I.; Class III., a special class for negatives developed in the new Eastman plate tank. The prospectus, which can be obtained from any dealer or by addressing a postcard to Kodak, Ltd., Clerkenwell Road, London, E.C., gives full particulars of the competition, including prize list and entry forms. The competition will be taken in three sections, closing respectively on August 21, September 21, and October 20, 1908, £80 being offered in each section, in amounts ranging from £1 to £15. Amateur photographers who are glass plate workers will doubtless be quick to grasp the opportunity of winning one of the attractive prizes offered by Kodak, Ltd., and the competition will doubtless represent a success which has attended previous contests of this nature organised by Kodak, Ltd.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received for consideration only, and are not accepted for publication without the approval of the Publishers, and advertisements are not accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Mr. H. E. Smith has made a step forward in the use of thinning agents by adapting them for use with P.O.P. A method is available which gives agreeable and permanent tones without use of gold, but closely resembling those obtained with the precious metal. (P. 490.)

An editorial article deals with the devices which may be employed in concealing the hand-camera when in use. (P. 487.)

Some notes on the personalia of the forthcoming Convention foreshadow a record meeting at Brussels. (P. 493.)

The eighth yearly handbook of the Professional Photographers' Association has just been issued. (P. 485.)

A case in which the delivery of postcards to time is concerned heard in the King's Bench Court last week. (P. 500.)

An ingenious device for helping the sale of frames for photographs has been described by an American art dealer. (P. 496.)

Flex cameras, photographs on china, and the telegraphic transmission of photographs are among the patents of the week. (P. 497.)

Last week's lecture by Dr. S. E. Sheppard on the chemistry of dyes dealt with absorption and the tanning of gelatine. (P. 479.)

Among the exhibitions now open are Mr. Benington's photographs at the R.P.S., and oil-pigment prints at the office of the "A.P." (P. 496.)

The exhibition of the Society of Colour Photographers closes to-morrow (Saturday) at 5 p.m.

## EX CATHEDRA.

**The Congress of Applied Chemistry.** The Congress of Applied Chemistry, an international body which hitherto has held its meetings on the Continent, will next year assemble in London from May 27 to June 2. The session of the Congress is divided into eleven sections, No. 9 being photographic chemistry, which will meet under the presidency of Sir William Abney. Many societies associated more or less directly with the chemical industries are represented in the organising committee of the Congress, and the support of foreign chemists is being obtained through committees in other countries. Further particulars may be obtained from the honorary secretary, Mr. Wm. Macnab, 10, Cromwell Crescent, London, S.W.

\* \* \*

**The Professional Photographers' Association.** The eighth handbook of the Professional Association is a summary of the present welfare of this body after seven years of activity. Those who have watched its career during this period can certainly credit it with having done much to carry out its avowed object, namely, "to improve the status of those practising photography as a profession; to defend their interests; to assist its members by advice, and to uphold the rights and dignities of the profession by all legitimate means." The current handbook shows in particular the aid afforded by the P.P.A. to its members in business matters, and we are glad to note the advice given on some items of business routine, the neglect of which frequently involves the photographer in dispute, if not in loss. As we have many times pointed out to those who have sought from us aid which it is out of our province to give, the professional photographer owes it to himself to be a member of the P.P.A., and, putting it on the lowest ground, we cannot recommend to him an equally remunerative investment for five shillings per annum.

\* \* \*

**Technique.** In Mr. Horace Mummery's very excellent lecture on "The Artistic Impulse," given at the R.P.S. at the last evening meeting, he dealt with the question of technique in the way familiar to every painter. That is to say, he took it for granted that in a work of art the technique must be perfect, or as nearly perfect as it is possible to make it. At the same time he pointed out that something more than fine technique was required to make a picture, and also that technique was so difficult to master in painting that many painters failed to acquire that something else. They had to devote so much of their time to the one thing that they were apt to neglect, or perhaps forget the importance of, the other. This is, of course, absolutely the right way to consider the question of technique, but we fear it is not exactly the way that many

photographers look at it, and we even doubt if all those who heard Mr. Mummery fully appreciated the force of his arguments. Good technique is certainly not looked upon as a *sine quâ non* by all photographers, and it is to be feared that some even follow exactly the opposite course to that laid down by Mr. Mummery. They strive for the pictorial "something more," but neglect the technique altogether. Possibly Mr. Mummery's lecture, when published, will do a little to convince them of the errors of their ways.

\* \* \*

**Competitions.** In the course of the discussion which followed Mr. Horace Mummery's lecture at the R.P.S., Mr. Hector Maclean made some very pertinent remarks with regard to the doubtful influence of exhibitions and competitions upon pictorial photography. His humorous sketch of the methods of the pot-hunter was full of point, and did not in the least over-state the case. Success in winning competitions, or in getting pictures accepted, is sometimes attributed to superlative artistic skill, and sometimes to luck; but there is another factor. A competition is not unlike a general examination. It is next to useless to fill a student with knowledge if at the same time you do not teach him how to pass an examination, and just as the art of "getting through" is a thing that can be learnt, so, no doubt, can the art of winning competitions. In the case of examinations, "passing" has long been a fine art, and this is so well recognised that the mere fact of having passed is no longer looked upon as a proof of knowledge. The passee may or may not be a very clever fellow, but judgment is reserved until by quite other methods he has shown what he knows or can do. Even now it is much the same with competitions in artistic work, and we fancy that many, even among competitors and judges themselves, are inclined to think with Mr. Maclean that competitions are of doubtful value.

\* \* \*

### The Commercial Side of Balloon Photography.

Apropos of our recent note of the proposed exhibition of balloon photography, a correspondent mentions how a West London photographer, debarred from entering the Franco-British Exhibition, made an ascent in the Dunlop captive balloon, and secured a number of excellent negatives. A year or two's time—when the photographer can hail an aero-taximeter—will doubtless see many examples of this kind of resourcefulness, and exhibition authorities will not find it so easy to sell sole rights of photographing if there is the aerial invader to reckon with.

\* \* \*

### A New Method of Combination Printing.

It is risky to describe anything as "new," and we are very doubtful if the method of combination printing to which our attention has recently been directed can be properly so called. For use in exhibition pictures actually hung on the walls of an exhibition gallery it possibly is new, but for other purposes it is undoubtedly old, for we have a dim recollection of having ourselves made use of it for pictorial purposes at about the age of two or upwards. It is a useful and very easy method, and the wonder is that no photographers seem to have used it in exhibition pictures before. There is no troublesome blocking out, no masking, no possibility of bad register, and no awkward joint to retouch. Neither is there any limit to the number of negatives that may be utilised. Whether we take two or twenty negatives does not matter. The work is just as easy, though the twenty may take up a little more time. Briefly, the procedure is this. Take two negatives, one for the sky, and one for the foreground. Make a print from each. Cut the bad sky off the good foreground print and

paste the remainder on to the good sky print. The foreground will thus be covered up, and only a good picture will remain. The proof of the pudding is in the eating, and the efficacy of the method can be studied at an exhibition that is being held within a hundred miles of this office.

\* \* \*

### The Paintings of Sorolla at the Grafton Galleries.

We heartily recommend a visit to Grafton Street for the pleasure and profit to be gained by a view of these remarkable paintings. Joaquin Sorolla is a Spaniard and an artist of the keenest and surest vision, with touch only surpassed by that of Sargent for directness and surety. His colour is dazzling and rich, and never cruel. In portraiture he is not always great, but his large array of small sketches displays great powers of truth and rapidity; whilst his larger landscapes and nudes in shades and shade are both subtle and broad. Not the least of his portraits is that of his father-in-law, Antonio Garcia, who stands holding a negative before his eyes, drying racks and other apparatus around him. He has also a portrait of "The Photographer Franzen" in the act of making an exposure with a large stand camera. We believe this is the first time that photography has served painter's subject-matter.

\* \* \*

### Photography in Finland.

Figures have been published in one of the German papers of the condition of professional photography in Finland, from which it appears that the sixty-two studios in the country give employment to 209 persons, and produce an output to the value of £22,500. Of the 209 employees, 151 are females—that is to say, there are two females employed for every male. Among the employees are twenty-eight foreigners, chiefly in the three most important towns, Finland, Helsingfors, Abo, and Viborg.

\* \* \*

### Chemical Synonyms.

Those who glance at the French and German periodicals may pick up information even if they are not familiar with either languages. Figures and formulæ are usually comprehensible, and, as Mr. Tony Lumpkin would have observed, such circumstances, is often the cream of the article. Here also there are pitfalls into which even those ordinarily familiar with the language have fallen disastrously. The Continental custom of writing the decimal point as a comma, and the comma (which we usually place before a set of three figures) as a full point, has led before now to some appalling transcriptions of French and German solutions. And the names of chemical substances are also open to confusion at the hands of the non-technical translator. "Soda" and "potasche" in German, for example, indicate the carbonates respectively of soda and potash, and not our caustic alkalies, soda and potash, which are written "Aetznatron" and "Aetzkali." And this, again, is a minor difficulty compared with "Unschwedligsäures Natrium," which the German easily rolls off his tongue in preference to our euphonious and convenient "hypo."

\* \* \*

### Silver Photo Salts and Subsalts.

One of the most interesting photographic exhibits in the Science Section of the Franco-British Exhibition is one by Major-General J. Waterhouse. This includes a number of specimens showing images produced by the action of light on silver and gold surfaces of various kinds, and a number of samples of the so-called subsalts of silver prepared by Wöhler's and E. Vogel's methods. In view of the fact that these, or very similar compounds, are continually being met with by photographic investigators, it

specimens collected here are of great interest. The variety of colour are very striking, and for purposes of reference and comparison it would often be useful to have such collection at hand. At first sight many of the specimens would probably never be recognised as mere combinations of silver with halogen, and similar combinations may often meet with, but mistaken for something else.

## DISGUIISING THE HAND CAMERA.

There are some subjects which are difficult to photograph where there is any outward evidence of a camera's proximity—street studies and groups in quaint, out-of-the-way neighbourhoods, for example. To exhibit an ordinary hand camera inevitably provokes curiosity, self-consciousness, even antagonism in the prospective subjects. In such cases it is good policy to mask or conceal the camera so that its nature is not perceived. There are, besides, numerous branches of work coming under the heading of secret photography in which a concealed camera is useful, and nothing of its possible employment, by the proper authorities, in the detection of crime. It is the intention of the present article to describe sundry simple methods by which the desired result can be accomplished. Let it be insisted, at the outset, that there is no excuse, in any circumstances, for taking photographs of individuals in groups against their will, or where it may reasonably be suspected that there would be an objection. It does not matter much that such a procedure is "bad form"; what is of far greater consequence is that it is unfair, unkind, and contemptible. There are, however, numerous cases where it may be taken for granted that no such objection would be made, but where the result would prove utterly failure through the conscious expression of the subjects if they were informed of the photographer's intentions.

The box-form magazine hand camera may be effectively concealed by wrapping it up as a brown paper parcel, tied with string in the usual way. It will be better to use a piece of packing of some kind, such as an old newspaper or a piece of cloth, round the edges of the camera to destroy the obvious shape of the parcel. In the front, where the lens is, a small portion of the wrapper is torn unevenly, forming roughly three sides of a square opening. The top fourth side of this rough square is left untorn, forming a flap, which is bent up when about to make an exposure but pushed down when the lens is not in use. An aperture of this description does not attract attention, while a neatly cut circular opening would probably do. A smaller opening with a flap is also torn for the use of the finder, with another one over the ground glass the latter. The string crossing the parcel lengthways is not quite central, or it will be in the way of the lens.

The brasswork of the lens should be hidden if possible; if necessary it may be blackened temporarily with black spirit varnish, which can afterwards be removed with methylated spirit if desired. Another good method, applicable to brown paper parcels, is as follows:—In the front, just above the lens, a large tie-on luggage strap is attached to the string that goes round the parcel. The strap is allowed to hang down, concealing the lens, when the camera is not in use, but is pushed aside, apparently by accident, whenever an exposure is to be made. The winding gear and the exposure lever must be made accessible by means of small tears in the paper, and possibly the lens itself may be completely disguised by gluing thin cloth loosely over the torn part, on the inside of the wrapper. As it slightly protrudes, this will look like the end of an inner wrapping, and will appear perfectly natural, while not impeding the working of lever or

release. That side of the parcel can be held against the body, away from curious inspection, when not in use. Some shutters may be worked by tying a short cord to the trigger release, and carrying it outside through a hole pierced in the brown paper. Pulling the cord will then depress the trigger. Small cameras may be wrapped up so that they form the front of a larger dummy parcel, which will be less likely to betray its real character than a smaller package.

A leather brief bag is a particularly unsuspecting looking article, and, if the worker possesses an old one which he does not mind spoiling, may be utilised very successfully for masking the camera. A hole is cut in one end, where the lens will come, as well as another smaller one for the finder, while the exposure may be made by means of a bulb and tubing arranged inside conveniently near the top. A few papers or bills of various kinds should be kept ready in the bag. The camera is prevented from shaking or moving by packing it round with soft paper or cloth. Then, when a photograph is to be secured, the worker stops, opens his bag, and taking out one of the papers appears to be reading it, or to be searching for something in the bag. In reality he is arranging the picture in the finder and pressing the bulb for the exposure. He then replaces the bill, shuts the bag, and walks innocently away. Even a reflex has been successfully worked in this way, using a rather deep bag. The openings in the bag for the lens and finder may be concealed, when not in use, by a strip of brown cardboard as nearly as possible the colour of the leather, which can be readily slipped in behind the holes or withdrawn at will. In some cases it may be preferable to place the finder on the top of the camera, so that it looks over the angle of the hinge when the bag is open; or it may be arranged in any other suitable position, as on the top of the bag near the handle, making sure, of course, that the image in the finder corresponds with that on the plate. The cheaper cloth or patent leather bags of the same shape are equally useful; so are small portmanteaux. There is no need for the photographer to face his subjects. He may have his side turned towards them, as if looking in quite a different direction, so long as the end of the parcel or bag is pointing where it is necessary. With a little practice, the finder can readily be looked at sideways, by a slight twist of the head; while in many cases the image can even be judged on its side, which, after all, is no more puzzling than the upside-down position given by the focussing screen of the ordinary stand camera.

An old waterproof or other garment, made into a parcel and carried by a leather strap, can be employed to conceal the camera. The latter is rolled in the centre of the garment, which is folded over at the ends. Flaps are then cut for the lens and finder openings, and for access if necessary to the shutter release and changing arrangement. The edges of the flaps should be loosely stitched round, to prevent confusion arising from the overlapping thicknesses of material. For this arrangement, a shutter worked by a bulb is the most convenient.

There is another method which can be used to give, at any rate, a temporary concealment of the camera; but this requires much greater dexterity and nerve. It is simply to carry the hand camera beneath an overcoat, rug, or similar article hung over an arm. It is quite possible to obtain a photograph in this way unnoticed, but it will be very difficult to get at the finder without betraying the artifice. There are some workers, however, who are capable of dispensing with the finder so long as the lens can be safely uncovered, and the above method may occasionally be useful to such, although for general purposes it cannot be compared with any of those previously mentioned.

Members of the daily growing army of lady photo-

graphers, who are often bashful of attracting too much public attention to their operations, may find many of the foregoing suggestions applicable to their own requirements, by a variation in the shape of the camera receptacle. A large hand-bag or reticule, for example, could advantageously take the place of the brief bag; the brown paper parcel is capable of many feminine amendments; and the strapped garment is quite within woman's own province. In addition, a good-sized muff may be mentioned as affording practicable cover for a small camera.

It is hardly necessary to say that any plan adopted for

masking the camera must be consistently and effectively carried out, or the photographer must not be surprised if the discovery of his seemingly guileful tactics should lead to resentment, perhaps shown in some unpleasant practical form. It is recommended as a counsel of safety never to make more than one exposure within a radius of any given spot. What passes unnoticed the time may be considered peculiar if repeated. In conclusion, it is particularly requisite, before commencing operations, to make sure that the lens is unobstructed, and none of the light is cut off in any way.

## THE CHEMISTRY AND PHYSICS OF COLLOIDS.

### III.

[The following is the abridged text of the third lecture by Dr. S. E. Sheppard at the L.C.C. School of Photo-Engraving, Bolt Court, Fleet Street, E.C. The two previous lectures have been reported in our issues of June 12 and 19.—Eds. "B.J."]

THERE is one phenomenon in colloid chemistry which I have already touched upon, but not dealt with specifically. That is what is termed "adsorption." The nature of this is still somewhat of a vexed question, and, to illustrate what is meant by it, I will instance certain particular cases. If powdered charcoal, purified cellulose, or silica dust, be wetted with a dye solution, much of the dye is removed from solution and associated with the solid. I say "associated," because the nature of the union is not absolutely clear. Again, in dealing with the swelling of colloid gels, which may be termed "absorption," part of the water is undoubtedly adsorbed. In the coagulation of colloids by electrolytes (salts, acids, bases), part of the electrolyte is taken down, and cannot be entirely removed by simple washing. Finally, in the mutual interaction of colloids, we again appear to be dealing with "adsorption." The substances composing the photographic image, whether in negatives on glass, in the various positive images formed originally by silver salts, or those due to pigment processes, possess great powers of adsorption, so it is worth while dealing with the question in some detail.

#### Adsorption.

The first question is, how does adsorption differ from ordinary chemical combination? Well, we have seen that the typical case of adsorption is the "taking up" by a solid of a dissolved substance, but we cannot speak of chemical combination, because on washing the compound formed the absorbed substance is continuously removed—in other words, on re-dilution, it goes back into solution, but a certain minimum remains.

#### Solid Solutions?

It is known that what are called "solid solutions" exist. For example, lead will diffuse into gold, and in several cases metals form mixtures which are not chemical compounds, in that there is no constant proportion between the components. Are adsorption compounds cases of solid solution? When a dye is removed by charcoal, reversibly, as instanced above, have we not a case parallel to the distribution of a substance between two solvents, as chloroform and water? In the latter case, however, there is a simple proportionality between the amount in each solvent, depending on the respective solubilities, which relation is known as Henry's law. This is not followed in adsorption.

#### A Surface Phenomenon.

Adsorption is very largely dependent on the state of division of the adsorbing body. The larger the free surface this presents the greater the adsorption. Hence porous and finely divided substances exhibit this phenomenon in a marked degree, and, as we should expect, colloid gels particularly. The "taking up" of dyes and inks is a case of adsorption, and it is evident

that the relative surface tension between the solid and solution plays a determining rôle. Properly speaking, adsorption should be limited to the case where the substance "adsorbed" settles out on the surface only: where it penetrates into the mass, we should speak of absorption. The dividing line, however, is hard to draw, especially in the case of colloid gels, where there is good reason to expect a very fine porous structure.

#### The Adsorption Law.

A variety of researches have shown that on bringing an adsorbing body into a solution, an equilibrium is soon reached, i.e., a state of rest in which the proportion of substance adsorbed to that remaining in solution remains constant, independent of the amount of the solid and the solution. This equilibrium depends, however, on the temperature, and also on the concentration, of the solution. The most systematic investigation is due to H. Freundlich's (*Zeitschr. Phys. Chem.*, 1906, 385), who found that well-marked equilibria were obtained. The amount adsorbed increases rapidly at first, then more slowly as a maximum is approached. Suppose  $a$  be the amount of dissolved substance,  $v$  the volume of fluid,  $m$  the amount of absorbing material, and  $n$  the amount adsorbed. The following equation was found to hold

$$ax = \lambda \frac{a - n}{v} m$$

where  $\lambda$  is a constant independent of the amount of adsorbed solid. Under certain conditions this may be written

$$\frac{n}{m} = ac^{1/q}$$

where  $c = \frac{a - n}{v}$  is the equilibrium concentration of the substance.

The ratio of  $c$  to  $\frac{n}{m}$ , or the "adsorption-coefficient," is therefore constant, as it would be if Henry's law held. This formula is in itself not of general validity. Thus, in strongly solved salt solutions, and with strong bases, the partition is more complicated.

#### Influence of Solvent and Dissolved Substance.

Adsorption is most marked in water, less in organic solvents. The nature of the absorbing material is of small moment. For acids are moderately, aromatic acids strongly, adsorbed. The influence of temperature is but slight.

#### Adsorption by Gels.

The adsorption most interesting to us as photographers is by hydrogels, such as gelatine, albumen, collodion, the

coagula, or precipitates, such as the silver halides, the original image, the image on P.O.P., etc. To begin with, part at least of the water taken up in "swelling" is adsorbed—i.e., is held by an attraction which is perhaps something between chemical and physical, or partaking of both. When this water is removed by desiccation, the vapour-pressure curve shows remarkable hysteresis, and at a certain point physical modifications occur, by which in certain gels the original clear gel becomes opalescent, pointing to a species of coagulation. There is reason to believe that such a structural modification takes place in gels that have been tanned are dried. Hydrogels also readily adsorb a large number of substances from solution. In microscopy the adsorption of dyestuffs is made use of in staining.

It must be understood that in such cases chemical reactions in the narrow sense also play a part—i.e., chemical combination between the gel, or a part of it, with the adsorbed substance, although in general no relation according to molecular proportions can be determined. But the chief action seems to be the concentration of the adsorbed substance on the surface of the adsorbing solid. Kieser, in experiments on the staining of silver halides by dyestuffs, found that the "grains" of silver were not stained throughout, but only an outer zone.

A particular case of adsorption of substances by hydrogels occurs when hydrosols are coagulated by electrolytes. In the case of emulsions, the precipitated halide takes down a certain quantity of electrolyte, usually the soluble bromide, and plays a part in the subsequent ripening. It will be remembered that one form of producing a colloidal solution, or hydrosol, is by peptisation—i.e., the action of a minute excess of electrolyte on the precipitated coagulum. This might lead, during ripening, to the production of a certain amount of hydrosol, hence to fogging. The question is dealt with by Lüppler in his valuable study of the "ripening process" (*Kolloidie und Photographie*, p. 97).

Salts which form soluble compounds of the silver halides are strongly adsorbed by them. Such are the alkali halides, sodium, potassium, thiocyanate, sulphite, etc. The adsorption of thiocyanate is shown especially in the use of this as a previous treatment with iron development. Furthermore, the use of thiocyanate to dissolve the silver halide leads to the formation of a slightly soluble silver thiocyanate, which are not retained or adsorbed by the gelatine. That is why fixing bath should never be used too far, and thorough fixation is necessary to free the film from silver. We shall come to this adsorption in considering colloid phenomena in printing.

#### Adsorption-compounds.

Adsorption-compounds are the complexes formed between the adsorbing solid and the substance adsorbed. Their composition depends on the manner of the adsorption-process, to wit, the concentration of the solution, the physical state of the adsorbing substance, temperature, etc., and no simple equivalent or combining weights are obtainable such as are characteristic of chemical compounds. Instances of inorganic adsorption-compounds are, for example, the amorphous complexes of ferric oxide with stannous oxide, lead peroxide with lead oxide, manganese peroxide and manganous oxide, and other colloidal oxides, ferric oxide with chromic oxide. Cassius' "gold purple," obtained by the action of stannous chloride on auric chloride. Zsigmondy has shown that this "gold purple" is formed when gold hydroxide is mixed with colloidal stannous acid, and that it is a colloid-adsorption-compound of the two, both similarly precipitated together by the electrolytes in solution.

#### Adsorption Phenomena in Photography.

The rôle of adsorption in photographic processes may be described as nothing less than essential and universal. The occurrence of the phenomenon has been long recognised, if under

other names, but we owe the clear delineation of a large number of cases to the researches of Dr. Lüppler-Cramer. The first case I shall deal with is the tanning of gelatine and other organic colloids, and from that we shall pass to colloid phenomena in negative making, and in the various after operations in printing, etc.

#### Tanning of Gelatine.

The tanning of bichromated colloids by the action of light is the basis of pigment printing, and of practically all photo-mechanical methods of reproduction.

When gelatine, albumen, fish-glue, are soaked with a solution of potassium bichromate, dried and exposed to light, certain changes take place, the most evident being the "tanning" of the colloid. That is (a) its melting point is raised, and it becomes insoluble (gelatine in hot water, albumen in cold water); (b) its swelling capacity is lessened or destroyed. With this is associated a differential absorption of dyes, such as is taken advantage of in pinatype and allied processes.

The chemical change in the tanning of gelatine is still somewhat obscure. I can only deal briefly here with the question, referring those interested to the work of Eder, Lumière and Seyewitz, Manly, and others. It appears certain that the potassium bichromate is reduced in light in the presence of the colloid, but it is not likely that the reaction depends upon oxidation of the gelatine. The accepted view is that a basic chromium chromate, of the constitution  $\text{Cr}_2\text{O}_3(\text{CrO}_3)_n$ , is formed, which unites with the gelatine. Further researches with basic chromic, iron, and aluminium salts, of which I shall speak directly, point to the conclusion that the active agent is colloidal chromium oxide, and that the "tanning" is due to the formation of a colloid complex or adsorption-compound of this with the gelatine. We shall see that the salts of chromium, iron, etc., are hydrolysed by gelatine, leading to the production of the colloidal hydroxides.

#### The Continuing Action of Light.

The insolubilisation of gelatine by bichromate is a process which takes place, in the presence of moisture, independently of light, which only catalyses the reaction. When partially exposed, the action passes from the insoluble portion to the rest, a change to which Abney gave the rather misleading name "the continuing action of light." Mr. Manly has proposed an explanation which appears sufficient. We consider, from the colloid chemical standpoint, that the compound  $\text{Cr}_2\text{O}_3(\text{CrO}_3)_n$  is not a true chemical compound, but an adsorption-compound, the components are in an easily separated condition, and provided there is sufficient moisture, can be separated by diffusion of the soluble component. Manly supposes that the  $\text{CrO}_3$  molecule wanders through the film, is reduced by the soluble gelatine, and tans the same, "but at the moment of formation of the  $\text{Cr}_2\text{O}_3$ , a molecule of  $\text{CrO}_3$ , chromic acid, is withdrawn from the ever present potassium bichromate. This newly acquired molecule of  $\text{CrO}_3$  is again dissolved, and travels further into the film to be again reduced to  $\text{Cr}_2\text{O}_3$  when it meets fresh gelatine." He points out that the action is a spreading one, which would, in time, render the whole film insoluble, and that temperature would increase the action by accelerating the diffusion of the  $\text{CrO}_3$ .

#### Tanning by Metal Salts.

In all cases of tanning by metal salts, it is noteworthy that the salts are such as are very susceptible to hydrolysis, and thereby to the formation of hydrosols, or colloid solutions of the hydroxides. In the presence of gelatine this hydrolysis is increased. Namias has shown that basic—in other words, hydrolysed—solutions of chrome alum have a much more powerful tanning action than the neutral or acid solution, and Lüppler-Cramer has shown that the essential is the formation of the hydrosol of the hydroxide (or oxide) of the heavy metal, which forms a colloid-complex, or adsorption-compound, with the

gelatine, coagulating the same in a solution. On this rests the use of citrates and oxalates as an addition to the bichromate sensitising bath. These form, with chromium, iron, etc., highly stable complex ions which are much less susceptible of hydrolysis, hence the sensitising mixture has less tendency to the spontaneous insolubilisation of the gelatine.

Uranium oxide salts also possess strong tanning powers for gelatine. Further, all the salts, both simple and complex, of the heavy metals, are strongly adsorbed by gelatine, though not necessarily with the accompaniment of tanning. The part

played by this action of adsorption—increased in the halide emulsions by adsorption to the halide or the gelatine halide complex—has been dealt with by Dr. Mees a writer, in dealing with Mr. Sterry's method of altering toning. The "desensitising" action of certain salts is due to their retention by adsorption and subsequent destruction of the "latent image."

According to Lüppo-Cramer, the numerous colloidal substances form adsorption-compounds with gelatine, leading partially to tanning, or completely, to tanning. S. E. SHEPHERD

## THIO SALTS FOR TONING THE BLEACHED SILVER IMAGE AND ALSO FOR TONING SILVER P.O.P. PRINTS.\*

[The following communication to the Royal Photographic Society by Mr. H. E. Smith, F.R.P.S., continues the latter's experiments on thio compounds in sulphide toning, but possesses particular interest from the fact that it records the successful use of these substances for the pleasing and inexpensive toning of P.O.P.—Eds. "B.J."]

CONTINUING some former notes on the use of thio salts of the chromium group such as thiomolybdates for toning bleached silver prints, the following brief particulars of some of the other compound salts I have tried may be but of little interest, as the practical value of these further salts appears to be slight, but a record of the experiments made may be of assistance to others. A matter of more practical importance seems to be the result of further experiments with thiomolybdates and thio salts of the chromium group as toners of P.O.P. prints, the tones being very near those given by gold and platinum, and of these recent experiments I give some particulars below.

First, then, as to the use of thio salts other than those of the chromium group referred to in my previous notes. Many compound thio or sulpho salts might be thought to be of use for the sulphiding of silver prints in the manner previously described, but the colours of the sulphides of the metals contained in these salts have to be considered, as well as the cost of their preparation as practical commercial articles. Also their stability when prepared is a very important point. For some or all of these reasons I consider that compound salts of the following types are not satisfactory for toning bleached bromide prints:—Sulphantimonates, thiovanadates, thiotellurates, thiohallates, thioarsenates, thioplatinates, thiotellurites. A good many other compound thio salts of somewhat similar types cannot be used for toning processes of this kind, as they are either insoluble in water or decomposed by it, or otherwise impracticable.

### Mercury and Schlippe's Salt

Schlippe's salt has been used mixed with sodium sulphide, but antimony sulphide tends to give too red a tone to please most tastes, if a sepia effect is wanted. Another suggestion that darker tones may be obtained with Schlippe's salt by the addition of a salt of mercury to the bleaching solution, seems open to objections from a chemical point of view. The use of mercury in a toning process is generally deprecated when one has in view the ultimate permanence of the print. In this case there would seem to be some reason to doubt the permanence of prints toned by such a method, as even if we assume that at the end of the toning process the mercury is present as  $\text{Hg}_2\text{S}$  or  $\text{HgS}$ ;  $\text{Hg}_2\text{S}$  (if this latter does exist at a temperature above zero) always contains some mercury ("Barfoed J.," Pr. 93, 230), and the red variety of  $\text{HgS}$  blackens by exposure to light, while the red or black variety may, with the  $\text{HgAgCl}_2$  in the bleached image, form sulpho-haloid compounds of the type  $2\text{HgS} \cdot \text{HgCl}_2$ . The reactions in this case would probably be complicated, and the results as regards permanence may well be regarded with considerable mistrust.

If permanence in the print is not required a mercury bleacher may certainly be used, followed by ammonium thiomolybdate, as Mr. Welborne Piper pointed out in "B.J." February 21, 1907, and the tone is good, but an acid clearing bath is necessary to prevent stains.

### Various Thio Darkening Compounds.

The following brief notes of the behaviour of some thio salts which are representative of the types of salts given above suitable for toning the bleached image may be given:—Ammoniovanadate  $(\text{NH}_4)_3\text{VS}_4$ . This is a beautiful salt so resembling potassium permanganate in appearance. Unfortunately its solution in cold distilled water, at first of a purple violet, quickly decomposes in the air, turning brown and depositing vanadium sulphide, while owing to the decomposition of the solution the odour of sulphuretted hydrogen is strong. Ammonium thioplatinate appears useless for retarding decomposition, as a freshly prepared solution of the salt, made alkaline with ammonia, lost its purple in fifteen minutes in a corked bottle half-full. Used as a solution, both with and without ammonia, it gives some intensification, but it stains the whites of the print badly, and this is difficult or impossible to clear.

Ammonium thioarsenate  $(\text{NH}_4)_3\text{As}_2\text{O}_5$ . The aqueous solution quickly breaks up, and the tone given by it is a yellowish brown, unpleasant for pictorial purposes.

Sodium thiohallate  $(\text{NaTiS}_2)$ . Crystals of this salt can be washed with alcohol, but with some loss. On treating with water the yellow crystals quickly decompose, the water dissolving out  $\text{Na}_2\text{S}$ , giving a precipitate of  $\text{Ti}_2\text{S}_7$ , so that it is doubtful if one can get a real solution of this salt. In any case the solution one does get gives poor tones.

Potassium thiotellurate and potassium thiotellurite gave experiments reddish brown tones after the style of those given by Schlippe's salt. The aqueous solution of this thiotellurite is unstable, turning in a short time from yellow to green and finally becoming colourless, leaving a greyish black precipitate, presumably  $\text{TeS}_3$ . The aqueous solution is one of the most stable of the thiotellurates, but does not give good tones.

Potassium thioplatinate, prepared by fusion, is unusually expensive to make, as one requires platinum black to start with, or a spongy platinum. The solution obtained by extracting the metal with cold water, tones badly and stains the high-lights. The bulk of the thioplatinate left is difficultly soluble in hot water. The saturated solution breaks up in the air with separation of sulphur, and re-crystallisation is not easy. The saturated solution from water is probably practically free from  $\text{K}_2\text{S}$ , but does not toning.

### Metallic Additions to the Bleaching Solution

But little of any very practical value seems possible in the way of adding an extra metal to the ordinary ferricyanide-bleaching solution, with a view to obtain considerable intensification of the bleached print when subsequently sulphided. Metals such as copper, bismuth, nickel, cobalt, tin, and platinum, for example, cannot well be introduced in any quantity in this way. Lead, mercury, and uranium can apparently be added, and though gold and mercury (if ammonium thiomolybdate is used to sulphide the bleached print) fair tones may be obtained, these tones seem to be good enough to be worth while running the clearing bath the high-lights, and the trouble of an extra bath (a clearing bath between bleaching and toning). With uranium

\* Patent of addition applied for 12341/08.

any way, the bleacher of course becomes an imperfect toning agent. With a certain ferricyanide-bromide bleacher that I use, a small portion of the precipitates formed by copper, bismuth, cobalt, platinum and tin salts seems to dissolve, but whether the metals are transferred to the bleached image, as lead, mercury, gold seem to be, I have not yet been able to determine. In any case, on sulphiding bromide prints bleached in such baths, there is no gain in intensity that I can detect, if ordinary alkaline bleaches are used. If the thiomolybdate sulphiding solution is the gain, if any, is masked by the intensification normally by this process, and it is difficult to judge on prints whether there is extra intensification or not.

In the use of copper one adds to the bleacher potassium citrate, for example, to facilitate the solution of the precipitate, one does not have a true bleacher, but a toning solution, and one may as well use the print at once by Ferguson's copper process (or the same ferricyanide toner in the case of this metal), and afterwards develop the result, which may of course be done. For uranium images alkaline sulphides must of course not be used, but a solution of sulphuretted hydrogen in water, and although in these fairly good tones may be obtained, the action of the sulphiding bath may be presumed to be only partial, if applied for a reasonable time, as nearly all the tone can be removed by sodium cyanate. With bromides toned by Ferguson's copper process, the sulphides or the thiomolybdate sulphiding solution may be the latter giving a rich tone; and as a strong solution of sodium oxalate has no apparent effect on the tone, the conversion of the copper salt into sulphide may be presumed to be complete.

### The Use of Thiomolybdate.

Returning again to the use of thio salts of the chromium group for sulphiding the bleached image, thiomolybdates containing a proportion of sulphur, such as, for example, ammonium thiomolybdate  $(\text{NH}_4)_2 \text{MoS}_4 \cdot \text{H}_2\text{O}$ , do not appear to offer any advantage over the normal thiomolybdates. Apart from increased difficulty of preparation in a pure state, there seems to be trouble often from metallic deposit in the shadows of the print, unless a small proportion of ammonium hydrate only is used in the solution, and the stain in this case is troublesome. Other salts may be used to replace potassium or ammonium in thiotungstate or thiomolybdates, such as barium strontium, calcium lithium, and manganese, which all form salts soluble in water, but many of these salts in common with most of those above mentioned are not so stable as compare badly with the thiomolybdates, etc., that I have recommended, as regards freedom from odour of sulphuretted hydrogen, owing no doubt to their instability. Barium thiomolybdate really requires distilled water to be used throughout, and solution is by no means free from odour. The strontium, calcium and lithium thiomolybdates give the prints a persistent yellow difficult or impossible to remove. The lithium salt is very objectionable in this respect. The iron and manganese salts cannot be recommended, especially the latter, which is very unstable. Much of the toning properties of potassium thiomolybdate, when it is prepared the native molybdenum sulphide by fusion, I attribute to the presence of iron thiomolybdate, from which the potassium salt is not freed. Mixing different thio salts together to form toning solutions does not seem to be of any practical use, for the mixed solutions in most cases do not keep well, and the increased complications in the chemical reactions seem to render the use of such mixtures undesirable.

### A Cheap Toner for P.O.P.

Coming now to the question of toning P.O.P. prints with thiomolybdates and allied salts, further experiments have shown me that these salts may be used with advantage for toning such papers. Thiomolybdate toning Cubrome "B" solution that has been put on the market for sulphiding bleached bromide prints is very suitable for this purpose and may be allowed to act on the P.O.P. print about the same time as recommended for bleached bromide, viz., 15 minutes. In this process the P.O.P. print must be first fixed in hypo (or ammonia or soda sulphite), as usual, and thoroughly washed, of course, in the case of hypo. The hypo bath may be rendered slightly alkaline with ammonia (though this is not imperative) or other of the usual fixing baths for which formulæ have been given. For P.O.P. prints may be employed.

After fixing and washing, the prints have, of course, usually an

unpleasant yellowish brown colour, but the toning solution applied as above recommended for about five minutes, has the effect of bringing back to a large extent the original density of the print, toning it, according to the type of printing paper used, to a colour that varies from a rich purple brown to a black tone, comparable with the tones hitherto obtained with the salts of gold and platinum. After toning, the prints may be rinsed, and the whites cleared with a bath of dilute ammonia applied for about two minutes and of 3 to 5 per cent. strength. In warm weather the 3 per cent strength is suitable. What is here meant by a 3 or 5 per cent. strength is 3 or 5 c.c. of .880 ammonium hydrate in 100 c.c. of water. After clearing the whites a final wash of about fifteen minutes completes the process. It appears to be unnecessary to wash the soluble silver salts out of the prints before fixing, as the omission of this usual proceeding when toning with gold before fixing does not seem to affect the final tone with this thiomolybdate process. Of course such washing before fixing may be done as a measure of precaution if preferred, or the soluble silver salts in the print may be converted into haloid salts of silver by the usual methods, such as a bath of sodium chloride (salt), sodium bromide, etc. I do not recommend sodium bromide for ammonia fixing. Any subsequent difference in the purity of the high-lights where this has been or has not been done is, however, difficult to trace, and I think it as unnecessary as washing before fixing in this case. Mr. R. H. Bow mentioned in the "Photographic Journal" for May, 1907, p. 245, that much time might be saved by fixing prints in ammonia, as the half hour or so usually necessary to wash out the hypo is practically saved. I think that the substitution of compound thio salts (such as ammonium thiomolybdate) for the alkaline sulphides (such as ammonium sulphide), previously used for toning prints that have been fixed in ammonia, will render Mr. Bow's quick fixing method more valuable, as with the thiomolybdate toning solution prints need not be printed so deeply as was necessary in the old ammonium sulphide process. Though the loss of depth in the fixing bath is, of course, the same, the thiomolybdate toning solution exhibits in this connection, to a large extent, the same important intensifying action that makes it so valuable for sulphiding bleached bromide prints.

### Print Somewhat Deeper.

The result with P.O.P. prints then is, that the loss of intensity on fixing the print as taken from the printing frame, is to a large extent brought back by the thiomolybdate toning bath, though not entirely, so that prints still have to be a little deeper than the finished result is required to be, some allowance being made for darkening on drying, which is rather a marked feature. Also the type of P.O.P. used affects the depth of printing, as mentioned below. This method of toning P.O.P. prints with compound thio salts such as thiomolybdates, thiotungstates, etc., may be used with advantage I find with practically all silver printing-out papers, gelatino-chloride, collodio-chloride, citro-chloride, albumen papers, and plain salted papers all taking good tones, though the tones naturally vary with the type of paper. The thiomolybdate solution has apparently no effect on prints that have already been toned with gold or platinum or on platinotype prints, or at all events practically none. Self-toning papers are also but little affected by such toning solutions, though sometimes a little extra toning effect may be got on these prints when of a bad colour, the shadows tending to a more violet tone on drying. Ferro-prussiate prints in the thiomolybdate toner are practically bleached to a greenish yellow.

### The Effect of the Printing Paper.

The tones generally obtained on different classes of P.O.P. papers may briefly be stated as follows:—Gelatino-chloride papers generally take a tone that is a rich photo-brown while wet, and which, on drying, becomes colder in tone and of a rich purple-brown, difficult to differentiate from an ordinary gold toned P.O.P. print. Collodio-chloride papers do not with the thiomolybdate toner generally take the purple brown tone referred to, but take on drying a practically black tone, comparable with the tone given by platinum toning. Collodio papers generally need to be printed only a little deeper than they would be for gold or platinum toning, as they do not lose so much depth in the fixing bath. Hypo seems the best fixing bath for these prints, as ammonia when followed by thiomolybdate toning on this class of paper sometimes yields slightly degraded high-lights presumably owing to insufficient fixation. On the other hand bronzed shadows caused by over-printing on these papers seem much

more amenable to the action of ammonia than hypo, and the ammonia in the thiomolybdate also helps to clear the bronzed effect from the shadows.

Albumen papers give tones from a rich photo-brown to a warm black platinum effect with thiomolybdate toner, and they require to be rather more deeply printed than gelatino-chloride papers, but the brand of paper may vary this a little, and of course I can only speak for my own experiments.

Plain salted papers with the thiomolybdate toner generally give from greys to warm browns, but the nature of the sizing substance used in their preparation, whether arrowroot, gelatine, or other, seems to affect the tone. If no sizing solution at all is used these papers are best fixed in hypo, as, in the case of some prints fixed in ammonia, I found that the thiomolybdate solution degraded the high-lights, probably owing to the silver bath sinking too far into the pores of the paper in the absence of any sizing. Hypo seems to clear this out better.

Thiomolybdate solutions as recommended for this process have, of course, the advantage over gold and platinum salts of being much cheaper, while the results should be even more permanent. There appears also to be complete absence of the double toning often met with in gold toning, while the

use of the thiomolybdate toner, as above mentioned, renders very practicable to fix prints in ammonium hydrate, effecting a great saving of time by eliminating the long wash fixing in hypo. This latter point should be of advantage in connection with work on the illustrated papers, where it is frequently necessary to make a print quickly for preparing a process. For press work of this description where time is often of importance, one ammonia bath, if plenty of solution be used, suffices, but it is much safer for ordinary work to use at least two or four ammonia baths of 3 to 5 per cent. strength for from three to four minutes each, and even with this precaution the process is much shorter than with hypo fixing, while the whites should be brilliantly pure.

In this process, after the final wash, it is always well to pass gently over the surface of the print a tuft of cotton wool or other soft material, to remove any deposit that may be formed by the action of the ammonia bath on the tap-water. Other compounds such as thioantimonates, etc., may be used in this process with some measure of success, but many of them stain the high-lights of the prints badly, and owing to their instability and other reasons are not really nearly so suitable for use.

HARRY E. SMITH, F.R.P.

[The following are the official instructions issued by the makers of the Cubrome thiomolybdate tones, Messrs. E. Edmund and Co. for the toning of P.O.P.]

The Cubrome thiomolybdate B solution will give with silver printing-out papers such as gelatino-chloride and albumen papers, etc., tones closely resembling those hitherto obtained with gold and platinum.

First fix the prints in hypo as usual (in this process a preliminary wash is unnecessary) and wash thoroughly. Then tone in the Cubrome thiomolybdate B solution for five minutes. The strength of the solution may be the same as for bromide toning, viz., five minims or drops of the B solution to the ounce of water. After toning rinse and clear the high-lights in a bath of dilute ammonia (3 per cent. to 5 per cent. strength) for about two minutes; a final wash of about fifteen minutes in running water completes the process.

The hypo bath may be made slightly alkaline with ammonia. If the washing water contains much lime it may be advisable to gently pass a tuft of cotton wool over the surface of the prints before placing them to dry, to remove any slight deposit.

As the thiomolybdate solution does not bring back all the intensity lost in fixing, printing has to be carried somewhat further than would be the case for gold toning.

Gelatino-chloride papers require to be printed rather deeply, and generally take a tone that is a rich "photo-brown" while wet, and which on drying becomes colder in tone and of a rich purple-brown, closely resembling a gold tone.

Collodio-chloride papers, as they do not lose so much in the hypo, do not require to be printed so deeply as gelatino-chloride

papers. Collodio-chloride papers do not generally take the pure black tone, but on drying are of a practically black tone, comparable with a platinum tone.

Albumen papers give tones from a rich photo-brown to a warm black platinum effect, and they should be printed at least as deeply as gelatino-chloride papers.

Plain salted papers take tones that vary somewhat with the nature of the sizing substance used.

For press work, where time is of importance, ammonium hydrate may be used for fixing, and a single bath, if plenty of solution is used, should suffice. The print should be kept moving in the bath (of about 5 per cent. strength), for from five to eight minutes when it may be rinsed and at once toned in the diluted B solution.

It is safer, however, with ammonia fixing to use from three to four baths for from three to four minutes each. For this purpose ammonia fixing is not advised for collodio-chloride prints or plain salted papers that have not been sized.

It will be noticed that the trouble of double-toning is done away with. The process is cheap, and when time is of importance at least half an hour may be saved by using the ammonia fixing method (which this process renders very practicable) instead of hypo.

Many prints may, of course, be toned together in a large dish, but they should be kept moving and not allowed to cling together. If prints are toned one over the other, as is sometimes done in gold toning, a longer time must be given, as the toning solution does not have free access to the prints.

#### CONVENTION LYRICS, No. 6.

There was a young artist of Bruges  
Whose feet were abnormally huge,  
So he let out his boots  
To convention galoots  
As a portable plate-changing ruse.

INTERNATIONAL PHOTOGRAPHIC EXHIBITION IN DRESDEN, 1909.—Photography in the Service of Ethnology will be demonstrated in next year's International Photographic Exhibition in the form of an industrial exhibition. The extent of this Special Exhibition, which will form a part of the Great Exhibition, will doubtless reach considerable magnitude, as a number of Home and Foreign States have promised their official participation. In this special exhibition all the civilised States of the world are going to show their characteristic beauties of land and people by means of artistic photographs. Objects pertaining to industrial art and ethnography will complete and give artistic finish to the whole, which will be placed in good architectural form by prominent artists of Dresden. This exhibition will undoubtedly serve greatly to open up fresh travelling grounds to

the travellers of all nations who are to be found in Dresden year after year, and especially at the time of the great exhibitions, and also increase the number of visitors to the foreign countries which are participating. The educative and ethnographical value of such an exhibition is also a matter not unworthy of consideration.

OXFORD CAMERA CLUB.—An interesting little ceremony took place last week in connection with the above club, when the members assembled to express their appreciation of the services of Mr. G. Norton, who for the past eleven years, has discharged the duties of honorary secretary, and to whose energy and zeal much of the success of the club was felt to be due. Sir William Herschel, president, on behalf of the members, said it was desired to express their thanks in tangible form, and he therefore asked Mr. Norton to accept of an eight-day chiming clock in oak case. Miss Ackland added a few words of appreciation on behalf of the lady members. Mr. Norton acknowledged the gift in a few well chosen remarks, adding that he felt sure the secretarial work connected with the club would be ably carried out by the two ladies who had succeeded him in that department.

## THE BRUSSELS MEETING OF THE PHOTOGRAPHIC CONVENTION.

at three o'clock on Monday, July 6, the official opening of the Convention takes place it will be found, unless every indication be falsified, that in the matter of membership the Convention of Brussels leaves behind the meetings of, at any rate, the past ten years. And the fact—for so it may be considered—is surely not surprising. Under the auspices of the Convention, and chiefly through the allied help of the president, Sir Cecil Hertslet, and the Association Belge and its president, Captain Van Bever, the members of the Convention will be able to spend a week in the chief artistic centres of Belgium, and will enjoy privileges in regard to photographing which a Belgian can obtain easily in all cases, and some not at all. The opening programme of meetings, lectures, and demonstrations is, moreover, a valuable part of the Convention programme, whilst the social side of a meeting such as that to be held at Brussels is, perhaps, as valuable a feature as any which figures formally in the printed handbook. The Convention has always succeeded in getting all its members known to one another, and this year, with the influx of Conventioners who are new or have not been seen for some years, the inducement to set out the week of July 11 for a visit to the Belgian capital is rather than usual. No wonder, then, as we hear from Secretary F. A. Bridge, that the applications for membership altogether exceed those of previous years. The annual subscription to the Convention, it should be explained, is 5s., whilst eligibility for membership simply amounts to a person's bona fides to take part in the proceedings with propriety.

### The President.

So uniformly fortunate in its presidents, the Convention this year is likely to be congratulated in seeing in that office Sir Cecil Hertslet, Majesty's Consul-General for Belgium. Photography has been Sir Cecil Hertslet's recreation for many years past—he was a juror of the photographic section of the Paris Exposition of 1900—but the claims of his official duties in the Consular service first at Antwerp and for the past five years in Antwerp have left him but scant opportunity personally to engage in the progress of photography. He has, however, kept closely in touch with what has been passing in his own and other countries, and his presidential address, it is anticipated, will touch on a number of topics which he, from his more distant standpoint, can observe in their true proportions to better advantage

than those of us who are in daily contact with them. The soul of courtesy and good nature, as Sir Cecil Hertslet is, the arrangements for the forthcoming Convention have had his personal interest and assistance to a great extent, and the visit to Antwerp, to conclude by an "At Home" in the Zoological Gardens, will be the day of the Convention week.

The president of the Convention comes of a family which has served the Foreign Office for two generations. Both his father, the late Sir Edward Hertslet, and his grandfather held positions in this department of the civil service. Sir Cecil's career commenced in 1868, when at eighteen years of age he entered the chief clerk's department of the Foreign Office. After some years in the Treaty Department he became Consul-General for the Departments of the Seine-Inférieure, Calvados, Eure, and the Orne in 1896, a position which he relinquished in 1903 to take up his present important duties in Antwerp. Sir Cecil Hertslet will be remembered for his interest in photography by members of the council of the Royal Photographic Society of twenty years ago.

### Some of Our Hosts.

Next, perhaps, to the president, the name of Captain Van Bever, president of the Association Belge, must be named as a moving spirit in Belgium for the reception of the Convention members. This is due largely to Captain Van Bever's efforts that members are to have unique privileges as to photographing in Antwerp, and if further proof were wanted of the Belgian president's enthusiasm in the cause of the Convention it is afforded by the fact that he has been taking lessons in the barbarous English language. Someone should surely have whispered to Captain Van Bever that there are limits to the sacrifices he is expected to make.

M. Vanderkindere, hon. local secretary of the Convention and general secretary of the Association Belge, has naturally had much to do with the Continental arrangements. With him also should be named M. Marissiaux, who will show on the Thursday evening his series of pictures of Venice. There are other members of the Association Belge who by their influence and assistance have ensured the smoothness of the machinery by which the members of the Convention are to see Belgium during the second week in July, and, lastly, we in England cannot forget the tireless energy of the one-man power

and the Convention, the hon. general secretary, Mr. F. A. ge.

### The Friday Excursion—Antwerp.

to set foot in Antwerp at 10 in the morning and to leave it at past five in the evening is to allow all too little time for the

M. Chas. Puttemans, Vice-President of the Association  
Belge de Photographie.

rial and historical attractions of this great city and mercantile e. The conventioners, moreover, is given the opportunity of present at a reception at the Hotel de Ville, of lunching at the d Hotel, of taking a steamer trip on the Scheldt, and of meeting

the president at the Zoological Gardens, altogether a bewildering programme for a brief day of 5½ hours. Antwerp, however, is a place so rich in material for the photographer that many may be tempted to remain there on the Saturday and to journey back to London on that day or Sunday via Harwich.

In a recent issue we drew attention to the beautiful surroundings in which this year it is the good fortune of the Convention to meet—namely, the “Cercle Artistique,” standing in the park of Wauxhall. We may now give the diary for the week, and refer all of our readers who would participate in the most enjoyable of photographic outings to place themselves in communication with Mr. Bridge at East Lodge, Dalston Lane, London, N.E.

### The Convention Programme.

The following epitomises the chief doings of the Convention:—

- Monday, July 6, 9.30 to 12.—Rendezvous, issue of tickets, etc.  
3.0.—Presidential address. Paper by Dr. W. Scheffer on “The Structure of the Autochrome Plate.”  
A Chat on the Far East. By Capt. Harfeld (with lantern slides).  
8.0.—Conversazione, exhibition, etc.
- Tuesday, July 7, 8.30 to 6.0.—Excursion to Ghent.  
8.30.—Annual General Meeting.
- Wednesday, July 8, morning.—Conducted parties in Brussels.  
4.0.—Photograph of Convention Group by M. Alexandre, before Palais de Justice.  
7.0.—Annual Dinner at Grand Hotel, Boulevard Anspach.
- Thursday, July 9, 8.30 to 6.—Excursion to Villiers la Ville.  
8.30 p.m.—Lantern séance of Belgian views by members of the Association Belge, explained by M. Vanderkindere, and of Venice, by M. Marissiaux.
- Friday, July 10, 9.0.—Excursion to Antwerp.  
4.0.—The President At Home, Jardin Zoologique, Antwerp.  
8.30.—Screen-plate photography and cinematography in science, F. Martin Duncan.
- Saturday, July 11, 9.30.—Excursion to Malines.

## STRAY THOUGHTS ON RETOUCHING.

a good number of years the “art” of retouching has been ded as one of the most important branches of the business of a sional photographer, until at last the careless operator seems imagine that any defect in the lighting, posing, focussing, or oping “can all be put right in the retouching.” Some, I really re, think that a mere smudge of a negative can be made into a one by the retoucher. It reminds one of the old days of en-silver printing, when the paper was home sensitised, and mp weather the whites of the paper became a little bit yellow, came all right in the fixing; but if there was a bad vignette, a print, or any other defect, the printer always said, “Oh, it me right in the fixing.” This was said so often that I believe ne was quite sure that if the print was from the wrong negative ould come all right in the fixing.”

course, the experienced photographer, who loves his work, s how really little can be done in retouching without injury to adation of the subject, and he should and does forget that is any such person as the retoucher, and work for the best without relying upon any other aid. Something may be done the pencil and the knife, or scraper, and for large surfaces varnish and pencil on the glass side. One great principle must s be borne in mind, and that is, the unpardonable sin of ng” is being found out. If it becomes discernible it is wrong ad. If it is not to be detected, and it improves the finished it is justified. For instance, I have seen a very good print in etipation of an old woman sitting by a fireplace, and it was seriously considered by the judges for a medal when one of

them discovered that the figure was lighted from the left and the fireplace, etc., from the right, yet it did not look wrong until the reversal of the surroundings was pointed out. It did not receive a prize.

### The Obvious Retouching.

The ordinary pencil work on a portrait should never be seen, and the most foolish criticism I ever heard of a certain retoucher's work was that the retouching could not be seen in the print. If it is properly done it should not be seen at all, any more than the “spotting” out of white specks. Yet thousands of retouchers have wasted years in endeavouring to acquire the power to “stipple” a face all over, so that they can make a negative print as though sand had been sprinkled over the face of the sitter. No one but a pofessional photographer ever admired such a meretricious effect. The sitters do not like it, I am sure; I have heard them say so. Then one hears a photographer say: “Ah, it's a very nice negative, but it just wants modelling up.” And they would have it stippled all over till the print looks like a photograph of a wax mask. And, of course, a nice white streak is put down one side of the nose, so that the sitter appears to have carefully greased it before the exposure was made.

Some will argue that the water-colour artist and the miniature painter stipple the faces of their portraits, and why should not photographers do the same? The answer is because the artist must put his colour on in dots to get an even surface; especially is this so with the miniaturist, who usually works on a non-absorbent surface, such as ivory, whereon washes are almost impossible. So

the photographers foolishly copy a certain result, which is merely a means to an end. The painter does not stipple because he likes to see it—it is not intended to be seen at all when the picture is viewed at its proper distance.

By the way, I wonder how many photographers know the origin of the word "miniature"; most people imagine that it is merely something small or minute. It really comes from "minium," the Latin name of a red pigment, which was used to paint the capital letters in Roman manuscripts, the other letters being in black. The manuscripts were what we should call "rubricated"—that is, the capitals were put in red. The "rubrics" about which we hear so much in ecclesiastic disputes were the directions in old prayer-books printed in "red" ink to distinguish them from the words to be said or sung, which were printed in black. In the course of centuries the red capital letters were decorated more and more till they became small pictures, and the miniaturist, who was at first only the man who painted the red capital letters with the pigment *minium*, became the artist who painted those exquisite little pictures in the capital letters of old illuminated Bibles and prayer-books; and thus those little pictures were called "miniatures."

No doubt the reader will say: "What on earth has it got to do with photography?" Well, of course, it has nothing at all to do with it.

#### Retouching Away the Likeness.

Another fault of the average retoucher is that he, or more often she, takes all the real character out of the face by "modelling up," and makes all sitters look alike. It is not difficult to make a flattering photograph of a sitter, which still is a fairly good likeness and recognisable. But photographs are often made quite unlike the original, and when the sitter shows it to friends they say: "It is a nice photograph, but I don't know who it is." And this is often the fault of the retoucher. A good portrait should show the sitter at his or her best, and a certain amount of retouching is necessary, although portrait painters speak of the "gross immorality of retouching." Yet those same people will paint most flattering portraits of their sitters, in which every small defect is left out and every good point carefully emphasised. An untouched portrait is often quite as unlike the original as an over-retouched one, and the true portrait lies somewhere between the two. If the negative is to be printed in rough platinum or gum bichromate, retouching is scarcely necessary, but as the ordinary photographer never gets a customer who wants such things, he need not trouble. The more usual printing methods, however, exaggerate incipient wrinkles and other signs of approaching age, besides freckles and other little blemishes, in an alarming way; but that is no reason why every sign of character should be polished off the face.

It is not often that a photographer has a difficulty in making a portrait of a lady sitter look old enough, yet I have had such an experience. I had a shock when a lady who did not look more than five-and-twenty introduced herself as the grandmother of Mrs. So and So's little boy of about five or six, photographed a few days before. I had to take the lady several times because she complained that all the proofs made her look so ridiculously young, and so they did. At last, by printing the negatives, with scarcely any retouching at all, we succeeded in making the photographs look old enough. But, of course, this is not at all a common experience.

OLD HAND.

#### AN INGENIOUS DEVICE FOR PICTURE-FRAMERS.

MR. J. H. BANKS, Fremont, Nebraska, U.S.A., sends to the "Picture and Art Trade," Chicago, the following interesting description of a device he has originated to show a complete frame from one piece of moulding:—"The first point involved in picture-framing is in obtaining the order. This is usually done by showing samples of mouldings. The ease with which the order is procured and the price obtained are governed largely by the environment of the samples. Soiled, dusty scraps of moulding pulled out of a pile, or uneven samples piled on a table, or hung up promiscuously in some corner of the shop, are not in keeping with the one essential feature that should predominate in this business—that is, everything should suggest and appeal to the artistic.

"My method of showing the samples being an original one, I concluded to give the readers of the 'Picture and Art Trade' an outline of it. I make a cabinet on the wall, in a light place, twelve

inches deep, four feet high, width governed by amount of space used. The background is covered with red felt, and is inclined so that the lower edge starts at the front of the cabinet while the upper edge leans to the wall. I then take three strips of wood, about the size of a lath, and saw notches like saw teeth every two inches above it, making room for three rows of moulding. I cut the mouldings fifteen inches long, mitre each end, and place one in the saw-tooth notch. The moulding is held in place by the incline and felt covering of the background.

"I cannot imagine how a frame will look by merely looking at a sample," is a remark every picture-framer has heard times and times over.

number. However, 'necessity being the mother of invention,' I decided to show a complete frame, with any width or colour material, from the one sample.

"This is done by a simple arrangement of two mirrors, 12 inches, placed at perfect right angles, high enough to show a sample of mat board and a picture sliding under it. The mitres of the moulding are placed against the two mirrors, and the picture, together with the one sample, forms the four sides of the picture. The mat is formed by the same method, by placing a mat in front of the moulding. A mat with a circular opening can be obtained by using a half-circle mat.

"The customers, by this method, see what they are to get, and of what they imagine they are to get, as in the case of the more commonly used; at the same time they are more quickly and easily suited and much more ready to pay the price you ask. Arrange your samples systematically as to size and colour, and by attention to the little details in the frame work, such as joining, retouching corners, filling nail holes, and sealing back, you will then have your framing department on a basis where you command a trade at prices that will be profitable."

## Exhibitions.

#### PRINTS IN THE OIL PIGMENT PROCESS.

THE "B.J." is perhaps to be excused for feeling some little gratification at the sincerest form of flattery implied in the opening exhibition of pictures by the promoters of the "A.P." and "P. and F." But whilst we bow, a misgiving seizes us as to whether photo exhibitions are going to be so plentiful as to be "ten a penny" in daily expectation of an announcement of a like event in the Street. Why should "P. and F." wait? The collection at Lord's includes 72 prints, a fair proportion of which Mr. Arbuthnot Evershed's, Mr. Wickison's, Mr. Gear's, and M. Puyo's, have been before at exhibitions. M. Demachy's beautiful and characteristic work is represented by four prints, but perhaps the chief object of the exhibition is to show the use made of the oil process by pictorial workers, who made a place for themselves in the few years before "oil" was thought of. Thus in 69, "A Wet Merde," we are glad to find Mr. James A. Sinclair appearing in the exhibition arena, and still more glad to see that the oil in his hands is not allowed to run riot. He, like Mr. Inston, "oil" to enhance, not to abolish, the photographic quality of work. Yet comparing a platinotype print from the negative of Mr. Inston, we cannot see that our good friend of Liverpool

much strength to his work by adopting "oil" as the vehicle. "Glimpse of Dovedale," No. 26, is a better argument for his advocacy of the new process.

It is easy to find examples of where the "oil" or "bromoil" process is used. Unfortunately the processes are not distinguished in the exhibition—break down in the rendering of the surfaces of objects. Mr. Hurst gets his snow to look like snow in Nos. 61, 62, and 65, and in No. 60 he fails, as does Mr. Rawlins in No. 6.

F. J. Mortimer, more than anyone else, has departed from photographic quality in his eight prints. He is something of a draftsman, and could almost as well have "knocked" off the four effects without putting up a camera. The photographic has helped him nicely with the drawing, but the results are unattractive, photographically. Mr. Marshall shows a tendency in some direction, but stops short at a point represented by No. 46, a canal scene, in which the oil process has been most cleverly introduced to introduce a light burning at dusk in the cabin of an old road-beamed vessel. Mr. Marshall has given us so many works, useful from a photographic aspect, that we sincerely hope he will be led away by the facility of oil into the unprofitable wastes of un-photographic.

# PHOTOGRAPHS BY WALTER BENINGTON AT THE ROYAL PHOTOGRAPHIC SOCIETY.

Benington has made some excellent pictures in his and they, in turn, have duly made for him a good reputation. Why are people not more content to rest upon their laurels? fifty pictures are perhaps twenty-five more than necessary for the preservation of his fame. His "Peace," "Church of England," and a few more almost as good are still a delight to see; but would wish that he had made a few more such before sweeping up his present fifty for exhibition. He has a fine feeling for his art, as witness the "Fleet Street from a Roof," where he throws his subject into brilliance and keeps his street in low tone. Alas, however, for the limitations of camera work! the low-toned street is unabashed all the strong sharp shadows caused by the sunshine that the artist has eliminated. Until this fact is the print is entirely satisfying. The sublime Stonehenge is spoiled by its granular sky, which has more "texture" than the stones themselves. We think Mr. Benington will make a better picture in the future than he makes with his present fifty.

## Patent News.

Patent applications and specifications—are treated in Mechanical Notes.

Following applications for patents have been made between 1907 and 1908:

No. 12,613. Improvements in pads for photographic purposes. Frank James Mortimer, 37, Chancery Lane, London.

ROOM LAMP.—No. 12,649. Photographic dark-room lamp for producing coloured light. Max Muthel, 33, Cannon Street, London.

WASHING-RACK.—No. 12,714. Improved washing-rack for photographic negatives. Carl Norman and Houghtons Ltd., 88, High Street, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PHOTOGRAPHS ON CHINA.—No. 11,849, 1907. The claim is for the transfer from a copper block which is made from a trans-  
fer.

The complete process consists as follows:—

A negative (preferably a reversed negative) is first made through glass or screens as in half-tone work or photo-mechanical. From this negative a transparency is then made and printed on a sheet of copper conveniently by the fish-glue method. The copper sheet is then etched deep enough to take the ceramic ink in and polished and printed from upon china transfer from which the print is then transferred to the china

article before or after glaze. The china article is then fired, and the result is a fine photographic reproduction upon the china. Thomas William Lascelles, Maybury Studios, Maybury Gardens, High Road, Willesden Green, and "The Illustrated London News and Sketch, Ltd.," Milford Lane, Strand, London.

STEREOSCOPIC SHUTTERS. No. 15,804, 1907. The invention relates to the construction of a shutter for stereoscopic cameras with the object of

1. Always obtaining, even in the case of rapid instantaneous work, a period of full opening of the shutter;

2. Enabling this period of full opening to be regulated between very wide limits, for example between 1 second and 1-100th of a second;

3. Ensuring that the closing of the shutter may always be effected at maximum speed whatever may be the period of full opening;

4. So balancing the moving parts that no vibration shall be transmitted to the photographic apparatus when the releasing mechanism is operated;

5. Mounting the plates of the shutter within the optical system so as to enable the diameter of the apertures in the plates and consequently the length and hence also the inertia of the plates to be reduced.

The specification contains the twelve drawings necessary for the explanation of the construction of the shutter. Jules Richard, 25, Rue Mélingue, Paris, France.

REFLEX CAMERAS.—No. 13,108. 1907. The specification describes an improvement in the camera protected by Patent No. 18,815, 1904 ("B.J.," August 4, 1905, p. 616), and the invention relates to improved means for raising the mirror quickly and releasing the shutter; for providing focussing extension, and adjusting the focussing hood. A pinion *a* is mounted upon the spindle *b*, which is driven by a segment of an interval wheel cut in disc *c*. This disc *c*, which we will call the rack disc, is pivoted to one of the focussing rack guides or sides of the camera *A*, and contains two slots or notches in its circumference, and the first of these slots *c*<sup>1</sup> engages with, and allows extra movement to, a pin or projection *d* on the leaf *e*, which lies adjacent to the rack disc *c*, and is connected by a short spindle *f*, to a thumb lever *g*, on the outside of the camera for operating same. The leaf *e*, which is pulled in one direction by a strong spring *h*, keeps the mirror *C* down on its seat at 45 degrees, and has a cam surface *e*<sup>1</sup> at one place, which, when the thumb lever *g* is depressed, passes a pin *j*<sup>1</sup>, fixed to a

projection *j*<sup>2</sup>, on a lever *j*, pivotted at *j*<sup>3</sup>. The lever *j*, which is connected to the shutter release *k* by the links *l*, is operated by a weak spring *m*, and is so arranged that its projection *j*<sup>2</sup> bears upon the periphery of the rack disc *c* until the slot *c*<sup>2</sup> thereon comes opposite thereto, when the spring *m* releases the shutter. George Russell Nicholls, Elm House, Gentleman's Row, Enfield; and John William Turner, of Turner, Son, and Hope, 88, Beaufort Street, Liverpool.

TELEGRAPHIC TRANSMISSION OF PHOTOGRAPHS.—No. 1,615. 1908.

The invention consists in the following process for the electrical transmission of photographic pictures:—A relief is reproduced on bichromated gelatine, and placed on a roller 2 at the transmitting station *A*, having a rotary movement around a fixed pin 3, so as to impart to it a translation movement. It is then traced by means of a stylus 4, fixed on a lever, which is only movable in its plane around an axis 6, the part of the lever 5 opposite the stylus 4 being angularly displaced, and its extremity describing arcs of a

circle, the length of which will be proportionate to the reliefs of the proof.

At this extremity of the lever 5 a commutation piece 7 is fixed, forming a slider adapter, to be displaced along a fixed resistance 8 or a row of contracts insulated one from another, and respectively connected with bobbins forming a resistance box.

Under these conditions, if the resistance 8 and the slider 7 in

Fig. 1.

series complete an electric line circuit of constant voltage, and constant external resistance, the absolute intensity indicated by any suitable galvanometer introduced in this circuit will vary according to the position of the slider 7, and consequently according to the relief of the proof 1 moving under the stylus 4 at the transmitting station A. A very sensitive mirror galvanometer is arranged at the receiving station B. Under the action of the variable line current the mirror will thus turn about its point of suspension.

If a convergent fixed luminous bundle of rays emanating from a suitable source 11 be projected on the mirror 10, passing through a lens 12, arranged in such a way that the rays emanating from the source 11 are brought to a focus on the mirror, this latter (considered in its turn as a luminous source) gives rise to a reflected pencil, which is displaced simultaneously with the mirror, and in a plane at right angles thereto, these displacements always corresponding to the variations of the line current, and consequently to the deflections of the galvanometer 9.

In the path of the reflected luminous pencil a converging lens 12<sup>1</sup> is mounted in such a way that the point of reflection of the mirror 10 always falls on its principal axis. If these conditions are exactly fulfilled, an image of the point *x* will be obtained at X, always at the same point of the principal axis, whatever may be the angle of reflection. At this point or conjugate focus of the luminous pencil traversing the lens 12<sup>1</sup>, the receiving sensitive surface 13 is placed (a photographic film, for instance), wound on a cylinder 14, having a rotary motion and a translation movement either identical with, or superior or inferior to, but always synchronous with, that communicated to the cylinder 2 carrying the proof 1 at the transmitting station A.

A scale 15 of shades, strictly graded, extending from black to white, is arranged on the path of the luminous pencil reflected by the mirror 10, before or behind the lens 12<sup>1</sup>, or even on this latter. By this arrangement the intensity of the luminous pencil emitted by the mirror 10 will vary like the different points of this scale, according to the position which the line current traversing the galvanometer 9 will cause it to assume, and consequently according to the variations of the relief which pass under the stylus

4 at the transmitting station A. Under these conditions it is evident that the luminous pencil reflected by the mirror 10 will make a more or less energetic impression on the sensitive surface 13, always proportionate to the reliefs of the original image 1.

By reversing the scale 15 of colours, that is to say, by causing it to turn through 180 degrees, the image recorded will be changed; it will then be positive, if the proof 1 at the transmitting station is negative, and vice-versa; further, by substituting for a normal scale of shades, scales of exaggerated or insufficient gradation, prints recorded will be then strengthened or weakened.

This practical apparatus may also comprise parts for supporting the essential devices, which parts have nothing to do with the working of the apparatus.

The receiving station is also completed by a dark room 16, closing the cylinder 14, this chamber having a single opening closed by a diaphragm 17.

It is stated above that the cylinder 14 at the receiving station may have a rotary movement and an identical synchronous translation motion, which movements are superior or inferior to movements of the cylinder 2 of the transmitting station. Evidently if these movements are identical the print at the receiving station will be of the same dimensions as the original. In the other two cases either an enlarged print or a reduced print will be obtained. Of course, in these two cases there must be co-ordination between the translating and the rotary movement, so as to avoid any deformation of the picture, and similarly the opening of the diaphragm 17 will be modified in a suitable manner in each case. Edouard Belin, 2, Rue Poncelet, Paris.

## New Trade Names.

CARMINAL.—No. 302,188. Chemical substances used in manufacturing photography, or philosophical research and anti-corrosives. N. and Hoare, 3, Cornwall Road, Stamford Street, London, Varnish and Japan manufacturers. April 11, 1908.

AZOL.—No. 302,671. Photographic chemicals. Johnson and Manufacturing Chemists, Ltd., 23, Cross Street, Finsbury, London E.C., manufacturing chemists. April 30, 1908.

The following complete specification, etc., is open to inspection before acceptance under the Patents Act, 1901:—

COLOUR SCREENS.—No. 11,698. Manufacture of screens or colour surfaces for colour photography. Dufay.

## New Books.

"Die Projektion Photographischer Aufnahmen." By Hans Schmalz. 2nd Edition. Berlin: Gustav Schmidt. Mk. 4.

This volume treats chiefly of the apparatus, appliances, and series of lantern projection. It devotes a few pages to the method of lantern slide making, and it briefly outlines the optical principles of projection systems, but the greatest share of its 222 pages is occupied by a consideration of the illuminants available for lantern projection types of lantern, screens, carriers, and so on. The author introduces to his readers the most modern for apparatus, such as the high power Nernst lamps, the incandescent spirit lamps, portable oxygen generators, and other recent inventions for the lanternist. There is a chapter on stereoscopic projection, and on the instruments (aphengoscopes) for the projection of opaque objects.

"Screens and Galleries in English Churches." By Francis Henry Froude, 6s. nett.

The author in this volume traces the evolution of the rood in ecclesiastical architecture, following its gradual development from the Rood and Rood beams of early Christian churches to the chancel screen and choir screen of the monastic churches. This volume is one which should surely interest architectural photographers to whom, more perhaps than to many other classes of photographers, a knowledge of the historical significance of the subject is of importance. Certainly if photographers are under any obligation to Mr. Bond, he is no less so to them, for, as he acknowledges, his wealth of illustration could never have been

ther but for the help of many photographers. The printers and publishers have done their part well in the reproduction of the photographs, and the result is a treatise which, with the liberal aid of the camera, retells a story, already written in stone, of doctrinal and ritualistic changes.

## New Apparatus, &c.

"Embossa" Press. Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W.

Scarcely a week passes but we are asked by some photographic publisher or local publisher of postcards for information on plate-marking cards, in which the view occupies a portion only of the card, the manner of the postcards issued by the large firms. Therefore we are particularly glad to see that in this small hand-press, placed on the market by the firm of Fallowfield, the postcard publisher in a comparatively small way is provided with the means of giving this enhanced appearance to his productions at a trifling out-

he "Embossa" consists of a small lever press, which will take photograph up to  $5\frac{1}{2} \times 3\frac{1}{2}$ , the standard official postcard. With the press are provided six sets of dies, giving plate marks of the following dimensions:—3 inches circle,  $4\frac{1}{2} \times 2\frac{1}{2}$  oval, 3 x 2 oval, triangles  $2\frac{3}{4} \times 4\frac{1}{2}$ ,  $2\frac{3}{4} \times 3\frac{1}{2}$ , and  $1\frac{3}{4} \times 2\frac{3}{4}$ . Any one of these dies corresponding plate is quickly inserted in the press and the plate of the die brought into accurate register by means of two screws shown in the drawing. After packing the die as may be required, according to the thickness of the card, a single smart turn of the lever will give to the postcard the desired plate mark. The lever makes it easy to insert or withdraw the cards rapidly, and any boy or girl can thus give this finish to a photographer's own postcards at a small expense for labour. The price of the "Embossa" is 17s. 6d.

"Lodge" Hiding Tent. Made by Sanders and Crowhurst, Shaftesbury Avenue, London, W.

A naturalist photographer has to be as full of devices as a surrealist if he would portray his timid subjects at close range. We have heard of Mr. Kearton's property cow and haystack it has been left to Mr. R. B. Lodge to put in the hands of photographers a simple and portable means of following in the footsteps of such pioneers in this difficult branch of photography as the Keartons, Mr. Pike, and others. The tent is an erection of canvas, of an almost neutral, dust or khaki colour, and is of dimensions so that it covers the operator and a reflex

camera (such as the Birdland) and its stand. A small aperture allows the lens to obtain a view of the subject, whilst the operator, standing, watches the focussing screen, or, seated, can observe the twig or leaf on which he has focussed. By means of tapes, branches and grasses are attached to the outside of the tent, and the photographer (see photograph No. 2) is enabled to disguise his presence as effectually as did the man who, pursued by the police

No. 1.—The "Lodge" Hiding Tent.

of Penge some time ago, thrice eluded capture by impersonating a small dustbin. Naturalist photographers must surely welcome this device, the want of which must many times have been sorely felt, as hour after hour passed and Mrs. Hedgesparrow refused to approach within range of the camera. On such occasions in the future the only words for the photographer's aspirations are, "Oh

No. 2.—The Hidden Lodge.

for a 'Lodge' in some vast wilderness!" Could Cowper have anticipated the trials of your modern field-row photographer? The latter at any rate will not grudge 18s. 6d. for the apparatus nor the task of carrying the 3lb. bundle on his travels. Others, too, may find quite distinct and commercial uses for the apparatus. If only the disguise can be made good enough to deceive, say, a creditor or solicitor's clerk, we can see a demand for the tent which must

exceed Mr. Lodge's wildest expectations. A hurried retreat to the back garden, and the "wanted" photographer has converted himself into part of the landscape.

The Medio Anastigmat Lens. Sold by John J. Griffin and Sons, Limited, Kingsway, London, W.C.

A very suitable lens outfit for the amateur photographer who wishes to do really good work, but requires to spend a comparatively small sum on one lens only, is provided by Messrs. Griffin in the "Medio" anastigmat, which is supplied in two sizes only, of 5½ and 6½ inches focus for quarter-plate and half-plate respectively. The lens is issued complete with the well-known and convenient

"Koilos" shutter, and the prices are but £2 7s. 6d. and £3 3s. The lens works at  $f/7.7$ , and though it is not advanced as equal in quality to the leading anastigmats, the definition is good, and, with some stopping down, the lens covers over a considerable angle excellently. The range of shutter exposures and the general convenience of the adjustments of the "Koilos" are other good points about the outfit.

#### CATALOGUES AND TRADE NOTICES.

**DEALERS ONLY.**—The new issue of the trade circular of Messrs. John J. Griffin and Co., Ltd., Kingsway, W.C., has just made its appearance, and will be sent regularly month by month to dealers who apply for it. Messrs. Griffin make a good suggestion to dealers as to increasing business (see page 3).

**THE WATKINS' METERS AND METHODS.**—A new catalogue of the Watkins Meter Company describes the complete list of those useful aids to practice which have followed in the train of the Watkins meter. The new list has a good deal to say on Mr. Watkins' recently introduced method of time development, and is also of general use for reference.

**THE ISOSTIGMAR.**—Messrs. R. and J. Beck, 68, Cornhill, E.C., have just issued a 28-page booklet, describing in detail the properties and working advantages of the Isostigmar lens. The list conveys, by aid of several half-tone reproductions, a useful idea of the lens, and particulars are appended of Messrs. Beck's special arrangements for the purchase of an Isostigmar, in exchange for another of their lenses.

**COLOUR PHOTOGRAPHY.**—The special summer number of "The Studio," 1906 (ready early in July) will be devoted to the consideration of colour photography and other recent developments in the art of the camera. Facsimile reproduction of colour plates taken direct from nature by the leading artist-photographers will be the especial feature of the volume, which will form a most fascinating and instructive review of the latest achievements in the photographic world.

**PHOTOGRAPHIC ASSOCIATION OF CANADA.**—The annual convention will be held in Toronto on August 4, 5, and 6. Subjects of practical interest to professional photographers will be discussed.

**BROMOIL PRINTS.**—Messrs. John J. Griffin and Sons, Ltd., ask us to say that the exhibition of Bromoil prints, formerly shown at the "B. J." offices, remains open at their Rendezvous, Kingsway, until the end of the present month. It can be visited during ordinary business hours.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JUNE 27.

Liverpool Amateur Photographic Association. Excursion to Ludlow.  
South Suburban Photographic Society. Excursion to Oxshott. H. J. Blain.  
Hackney Photographic Society. Excursion to Otters Pool.  
Southend-on-Sea Photographic Society. Trip in a Leigh Bawley.  
North Middlesex Photographic Society. Outing to Denham. A. E. Smith.  
Handsworth Photographic Society. Excursion to Sutton Park.  
Chelsea and District Photographic Society. Outing to Heston and Hounslow.

MONDAY, JUNE 28.

Southampton Camera Club. "The Sinop Process of Collotype Printing." Yerbury.

TUESDAY, JUNE 30.

Hackney Photographic Society. "Photographing and Printing Clouds." Capper, J. Linley.  
Manchester Amateur Photographic Society. "Figure Studies in Sun." J. Shaw.

WEDNESDAY, JULY 1.

Leeds Camera Club. Excursion to Adel Woods.  
United Stereoscopic Society. "Artificial Light Photography." P. Dennis.

**EDINBURGH PHOTOGRAPHIC SOCIETY.**—At the annual meeting of this Society on June 3, the following office-bearers appointed:—President, Mr. J. F. Duthie; vice-presidents, H. Stewart Wallace, W.S., Mr. R. C. Malcolm, Advocate; secretary, Mr. J. S. McCulloch, W.S.; hon. treasurer, Mr. B. Peden, C.A.; hon. survey secretary, Mr. James Oliver; curator, Mr. John Anderson, and twelve members of council. Annual reports were adopted, and interesting details were of the important work which the society is doing in connection with the survey of Old and Modern Edinburgh. An enthusiastic spirit prevailed in the meeting, which augured well for session, in connection with which a splendid programme of meetings has already been prepared.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At a meeting on Thursday, June 18, the hon. sec., Mr. Ernest H. showed an entirely new reflex camera which will shortly be upon the market, and which is novel inasmuch as it is fitted with a swing back.

The camera, of which Mr. Human is the patentee, attracts much attention, and was greatly admired by all present. The back is so arranged that the true image is always shown the top focussing screen whether the back is moving or not, the planes (of the focussing screen and plate) moving together in connection with the mirror. As an example of the range of movement was mentioned that holding the camera in the hand, and from ground level, it was easy to include the whole of the Westminister Cathedral, using a six-inch lens.

## Commercial & Legal Intelligence.

**THE DELIVERY OF POSTCARD ORDERS.**—Before Mr. J. Channell, in the King's Bench Division of the High Court of Justice on Wednesday and Thursday of last week, a case was heard in the Receiver for the debenture-holders of the Cerio Photo Printing Company, Ltd. (in liquidation), of London and St. Albans, Messrs. Birn Brothers, fine art publishers, of Bunhill Row, E.C. 4, £183 in respect of goods sold and delivered. The defendant counter-claimed for breach of contract. Mr. Collins was counsel for the plaintiffs, and Mr. Lewis Thomas, K.C., with Mr. J. Emanuel, appeared for the defendants.

Mr. Collins explained that in November, 1906, the Cerio Printing Co. entered into a contract to supply Messrs. Birn with 720,000 picture postcards of actresses printed by a new process which was claimed to be superior to the ordinary "black and white" photographs. The photographs, however, were not in accordance with sample, and, in consequence of repeated complaints the defendants wrote that the plaintiffs must cease deliveries. The plaintiffs admitted the justice of the complaints and replied that the defects of the work were due to mechanical and chemical difficulties which they hoped had now been overcome. Nevertheless the defendants refused to accept delivery of any more photographs.

en, later on, the Receiver for the debenture-holders of the Company wrote to them pointing out that they owed the Company a certain sum of money the defendants replied through their lawyers that although this was so, they had a far larger claim against the Cerio Company in respect of breach of contract. The claim, however, Mr. Collins pointed out, was that the defendants were unable and unwilling to deliver the balance of the claim. The answer to this was that the defendants themselves had demanded the order.

Ernest Wm. Gundry, the Receiver for the debenture-holders, produced evidence that the sum claim appeared in the books of the Cerio Company as due from the defendants.

There was no other evidence for the plaintiffs, and the counter-claim proceeded with.

Thomas said his clients placed an order, at the end of 1906, with the Cerio Printing Company for 10,000 copies of seventy-two photographs of actresses. The plaintiffs represented that they had a method of producing brown or sepia-tinted photographs commanded a more ready sale than the ordinary black and white. The offer was accepted and the goods were to be delivered in instalments, in accordance with a sample submitted at the time the order was made. Counsel explained that at certain times when the demand for the photographs was much to the fore their photographs commanded a high sale. During the run of a popular comedy, for instance, the photographs of the actors and actresses would sell well, but when the demand was over there would be no longer a demand for photographs of particular poses. Therefore a rapid delivery of such goods was essential. But instead of fulfilling the terms of the contract the defendants could only promise the proofs by January 4, whereas the order was made on November 20. When deliveries were made the photographs were received from dealers of the bad quality of the order and these were continual up to March. The defendants then wrote declining to take any more of the photographs. Albert Elsner, one of the partners in the defendant firm, produced that each year they placed on the market 2,000,000 postcards of actresses. Referring to the contract entered into with the plaintiffs, he said that the specimen shown him by Mr. Thomas, the company's representative, was equal to any of the best. The company promised to supply photographs equal to the specimen. Although Mr. Fry made a note on the back of the specimen that delivery was to be made within one month, and it was at the end of November, they did not get the first samples for the plaintiffs to sell from until January 4, and stock began to come in very slowly at the end of January. There were constant complaints from customers of bad printing.

Mr. Collins pointed out that the defence, in their pleadings, only asked for delay in delivery, and made no claim in respect of the quality of the photographs.

The Judge: That is my difficulty. I think they have counter-claimed on the wrong thing. They have claimed for damages for not delivering the balance of the goods which they refused to accept, but they made no claim in respect of quality, as to which the counter-claim seems to indicate that they had a good case.

In cross-examination Mr. Collins called the witness's attention to the fact that the letter embodying the terms of the contract between the plaintiffs and the defendants did not contain any reference to delivery within one month. The witness replied that the details were fixed subsequently. He then supplied the photographs from which the Cerio Company had made the postcards.

Mr. Collins: Did not the plaintiffs complain that the photographs supplied were flat and produced bad negatives?

Witness: No. The fact that the cause of the trouble was that your photographs were inferior?—They were good photographs by the best photographic standards.

The Judge: Photographs of actresses. Do they cease to be popular when the popularity of an actress changes as often as the fashion of a woman's dress. There is a fluctuating demand for a particular actress's photograph. Witness explained that the popularity of an actress would be produced and for a time they would be in vogue. Then another twenty would be produced and the demand would lose their popularity.

The Judge: Then it is the photographs which lose their popularity when the actresses are no longer popular?

Ernest Wm. Gundry, the other partner in the defendant firm, also

gave evidence. He said the process introduced to them by the Cerio Company was decidedly new, at the price quoted—viz., between four and five shilling per gross.

In cross-examination witness admitted that the market for these particular photographs was not past at the time they refused to accept any more deliveries from the plaintiffs. If the quality had been better they could have sold them.

The Judge remarked that the defendants would have had a good case if only they had pleaded the right answer.

Mr. Thomas said he thought the pleading of the counter-claim as it stood covered the plaintiff's claim. Seeing that the Cerio Company was in liquidation it was not worth while to seek heavy damages from them, and the defendants only wished to cover by their counter-claim the amount of the claim against themselves.

Frank Edgar Fry, called for the defendants, said he was in the employment of the Cerio Printing Co. from the time of its formation to the winding up, and carried through the negotiations with the defendants. The photographs were to be produced according to a secret process of a Mr. Wagner, who was employed by the Cerio Company to carry out his process. The inventor was not able to produce large quantities at the same standard of quality as the specimen on which the order was given, and complaints were made repeatedly by the defendants up to the end of April, 1907.

Mr. Thomas: At the end of May were you in a position to deliver these goods according to quality?

Witness: I am afraid not. Things were getting worse.

But you wrote on June 5 that you thought your troubles were at an end?—Yes, but one has to be sanguine in business.

The Judge: Then your letter was a little bit of trade humbug.

Witness: I was under the impression when I wrote that the company would turn to the bromide process, but they did not do so, and shortly afterwards went into liquidation. The company was never in a position to fulfil the contract.

Replying to Mr. Collins, witness said he was now in business as a photographer on his own account, and had done business with the defendants.

This concluded the evidence, and Mr. Thomas, addressing the Judge, contended that the facts did not justify the plaintiffs alleging in their pleading that the cancellation of the contract was an amicable arrangement between the parties. It was perfectly clear there had been a breach of contract, and the damage sustained by the defendants was far in excess of the plaintiffs' claim.

Mr. Collins, dealing with the counter-claim, said the defendants relied for their claim in respect of delay upon a written contract in which nothing was said as to the time of delivery. It was clear from the correspondence that delivery was to be within a reasonable time, and therefore, counsel submitted, the claim for damages for delay was answered. After March 23 there did not appear to have been a single complaint as to quality, but the defendants did not claim for damages in respect of the earlier deliveries, which were admittedly defective as to quality. The contract ultimately appeared to have been mutually rescinded.

His Lordship, in giving judgment, alluded to some of the difficulties of the case, notably the differences between the written contract and the memoranda which preceded it. Nobody seemed to be clear when deliveries were to commence, or at what rate they were to continue. Presumably a reasonable quantity was to be delivered in a reasonable number of weeks. During the whole time of the deliveries there were complaints as to quality, and if the defendants had counterclaimed in respect of this and proved their case he would have held that they were entitled to recover. It might be that the defendants recognised a difficulty in proving it. Their complaint was damage to reputation, but unfortunately that was a damage not recoverable at law. In reply to the claim which they had put forward—viz., breach of contract in respect of delivery, the plaintiffs said that delivery was dispensed with by the defendants cancelling the order, and *prima facie* this was so. He had come to the conclusion that the breach was not one in respect of which the defendants could get damages. He took the letters of the defendants cancelling the order to mean, "Don't deliver any more; we won't ask you for any more, but we will put another set in your hands if you give us a written guarantee as to quality and time of delivery." The inference seemed to be that the defendants did not think then that they had such a contract as they were now saying they had, and were suing for damages

upon. He did not think the defendants had proved the refusal of the plaintiffs to deliver the goods. At this time the plaintiffs were professing to have got rid of their difficulties, and it was a question whether the defendants, before they could say there was a breach, should not have given the company an opportunity of showing whether their professions were true. Plaintiffs must have judgment for the sum which the defendants had admitted.

**A NORFOLK BANKRUPTCY.**—The examination of Mr. Scott Stanley Meale, of Coltishall, Norfolk, was held at the offices of the Official Receiver for the Norwich district last week. The summary of accounts showed gross liabilities amounting to £580 12s. 2d., and a deficiency of £77 0s. 2d. The cause of failure as alleged by him was bad trade. The Official Receiver, in the course of his observations, said: A receiving order was made on the debtor's own petition, consequent upon three creditors having obtained judgment against him. The debtor commenced trading as a grocer at Coltishall in April, 1896, with a capital of £45. A few months later he opened business as a photographer in the same premises. Debtor states that in April, 1907, he purchased his premises at Coltishall for £420, the greater part of which he obtained upon mortgage. The books kept comprise a cash book (not written up since last Christmas), daybook, and customers' ledger. The fully secured creditors are the several mortgagees of the premises which the debtor occupies. The partly secured creditors are the debtor's bankers, who hold a policy on his life. The whole of the unsecured liabilities are in respect of trade debts. Eventually the estate was left in the hands of the Official Receiver.

## News and Notes.

**PHOTO-CHEMISTRY** was the subject specially selected for discussion at the recent Congress of the Bunsen Society in Vienna. Dr. Luther of Dresden, in the introductory paper, deplored the fact that, notwithstanding the extensive range of photo-chemistry and its importance to science and industry, one small portion of it only—photographic chemistry—had up to the present received more than very scant attention. While in electro-technology an efficiency of 99 per cent. had been reached, and the steam engine had been brought to a high state of perfection, in photo-chemistry we had accomplished practically nothing. We were using up our reserves of coal, which represent immense stores of energy acquired through photo-chemical action, and had not commenced to devise a substitute to replace them when exhausted. Nearly all we know in the way of general laws governing photo-chemical reactions might be summed up in a few words: Light nearly invariably favours chemical change, seldom or never retarding it; the progress of the reaction is proportional to the amount of light and dependent upon the concentration in the reacting material of a certain substance which is to be regarded as the light-affected body.

Dr. Frank dealt with chemi-luminescence, defined as the emission of light during a chemical change without development of a high temperature in the system. Whether it be due to the glowing (ignition) of minute particles within the luminous mass, or to simple light emission from the whole, is not known; nor can we say if the phenomenon is reversible, i.e., whether communication of light to the material would develop the chemical change.

Professor Stobbe drew attention to the importance of a study of photo-chemistry towards elucidating such changes as occur in the oxidation of glue, gelatine, and albumen; photography would benefit by improved knowledge upon these decompositions. Other significant examples cited were the splitting of acetone into acetic acid and water, the bleaching of asphalt, and the fading of dyes.

Professor Schaum, of Marburg, discussed the change in the silver salt of the photographic plate, and expressed the belief that first a subhaloid, and from this a further intermediate product, was formed before metallic silver was set free.

A remarkable observation has been made by Dr. Scheffer, of Berlin. His sections of the gelatine emulsion under various conditions, greatly magnified upon a screen, showed that during development small "germs" and "spores" of silver shoot out from the granules of silver salt, gradually spreading at the expense of the latter.

Major-General von Hübl, of Vienna, exhibited a number of very

fine specimens in three colour films taken in natural colours, Lumière's Autochrome plates, and drew attention to the very faithful manner in which the hues were reproduced, particularly the grey shades very difficult to match.

**VOICE PHOTOGRAPHY.**—A method of voice photography has been discovered by Dr. Devaux-Charbonnel, a medical practitioner. An account of it was given by M. Poincaré at the Paris Académie des Sciences meeting last week. It appears that vowels and consonants pronounced before a microphone connected with a Blondel oscillograph, can be impressed on a photographic plate in the form of curves characteristic of each kind of sound. The curve of a vowel shows a regular recurrence, whereas the consonant sign does not recur. With a little practice, therefore, it is possible to decipher vowels and consonants and to read a page of the photographed words. By means of this method, explains Dr. Devaux-Charbonnel, it may be possible to read a telephonic communication made in the absence of the person for whom it is intended. The apparatus placed before a telephone, would photograph on a sensitive film the words heard in the receiver. The photographic signs may be read in the same way as one would read a page of shorthand. Devaux-Charbonnel also states that Mr. Duddell, the well-known English consulting electrician, suggests that it may be used for photographing the voices of criminals. "In conjunction with the impressions, this would supply an absolutely reliable, absolutely perfect means of identification." The apparatus has still to be perfected.

**PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.**—The annual visitation arranged by Mr. Hector Maclean, F.R.P.S., will be held on Saturday, June 27. Dorking, Betchworth Park, Basingham Green, and Leigh will be visited, and opportunity afforded for photographing the ancient moated residence, Leigh Place.

**THE DEATH** is announced of Count Carlo Piscicelli-Taeggi, president of the Società Fotografica Italiana. The deceased gentleman had been a most zealous worker in Italian photographic circles for many years.

**THE "RAJAR" CAMERA**, offered monthly by Messrs. Rajar, Limited of Moberley, Cheshire, for the best print on "Rajar" P.O.P. has been awarded to A. Baugh, 106, Bowyer Road, Salford, Birmingham, this print having been judged the best during May. The paper on which the print was made was purchased from Messrs. Hurman, Limited, Victoria Square, Birmingham.

## Correspondence.

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\**We do not undertake responsibility for the opinions expressed by our correspondents.*

### THE COST OF A STUDIO.

To the Editors.

Gentlemen,—With reference to the query of "At Present Amateur," re "Cost of Studio," in the "B.J." of to-day's date, I may say that a rough method of arriving at the approximate cost would be to price the cubic contents of the proposed building at 10s. per foot, for which amount a fairly substantial studio should be built under ordinary conditions. If the querist has proper plan and specification he can, of course, obtain competitive tenders from one or more local builders, without binding himself to accept the lowest or any tender.—Yours very truly,

DRINKWATER BULLOCK.

St. Anthony's Studio, 24, Queen Street, Hammersmith, W.,  
June 19, 1908.

### TONING BROMIDES—REFUSAL TO BLEACH.

To the Editors.

Gentlemen,—I recently met with the first refusal of a bromide print to bleach (in a ferricyanide bath), for which I was unable to account. The print was a 12 x 10 enlargement, on Kodak bromide paper. I was making some ozobromes in a bath which some weeks old, but which had just given an excellent print. The above bromide was made a few days before, and had been well washed.

1. The subject (as you will see from enclosed waste contact in same negative) consists of light half-tones (drapery, etc.), deep shadows against a black background. I used the method of ozobrome, and on separating print of tissue found, surprise, that the black parts were almost bleached, but the shadows were not altered. The tissue developed with a corresponding wash, re-developed, washed, and dried the bromide. Placed it in a bleaching bath to tone it, but the half-tones refused to bleach, the blacks bleaching perfectly. I again developed, etc., and a few days after tried it with a newly bleached, with the same result. The print is now the same as first made, except for a slight rustiness through re-development cannot send the print for testing, as I have not the negative and it is the only enlargement I made. It is an outdoor scene from which I have worked out the background in the negative should mention that I have always successfully toned prints on paper, except this one, and have made ozobromes with it. I have toned any others of the same batch of paper I can remember now. The developer throughout was diamidophenol.—Yours, etc., D. B. (Manchester).

I have heard of one or two cases of this difficulty, but the case of the half-tones and high-light resisting the bleacher, shadows succumb to it, is unknown to us.—Eds. "B.J."]

#### WRITTEN TESTIMONIALS—A CAUTION.

To the Editors.

men,—Having experienced a case myself which is of very importance to the profession, I think it is wise to caution persons to be careful in giving written references to their friends on leaving them.

The case is this:—About eighteen months ago, on dismissing an assistant, he asked me to give him a written reference. To help him out, I gave him one. Last summer, being again in want of an assistant, and this same assistant asking to come back, I engaged him, on a short time, as things were not satisfactory to me, I dismissed him without any reference. After a few weeks this assistant, on his own nearly opposite my business premises, put up a case and (not having any studio) canvassed all the photographers in the hood. In the show case he had my reference, framed and in a conspicuous position with a notice to the effect that his reference was equal to any, as shown by "your own townsman." This reference has been there (and is still) for weeks. If this is not a most unprincipled, unscrupulous, and unprofessional dealing I will not judge.

The editor tells me I should sue him for damages under false pretences, etc., as the reference was used entirely different and to what it was given for, and against my business.

In giving this in the interest of photographers, and should like to see comments by others on this subject of giving written references. In future, for myself I shall only give to those who ask me to engage any late assistant of mine. In fact, I often get a farce.—Yours truly, MARCUS.

Unpleasant reasons the name of the writer of the above letter is. Nevertheless, the incident may have its moral for photographers.—Eds. "B.J."]

#### SCULPTURE OR PHOTOGRAPHY.

To the Editors.

en,—At the exhibition just opened in Long Acre I have been scandalised by recognising in the print, No. 36, "The Girl," Bertram Park, a photograph from a statue exhibited at the Royal Academy in 1890 by the late E. Onslow Ford, R.A. The result of the oil process has enabled the printer to colour the statue of this piece of statuary so as to rob them of their own work. Dr. Evershed and Mr. Mortimer were with me and former asserted that the photograph was from flesh; the latter nothing on the point. Thenceforth neither did I, for I am sure. It may be that Mr. Bertram Park has a legal right to use the statue in this guise and without acknowledgment; but whether he has a moral right to tamper with a work of art of our most talented, most lamented, and most respected sculptor, especially as he gives no indication that the credit of it is due to himself.—Yours truly, F. C. TILNEY.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

A. Russell, 6, Wilde Street, Liverpool. Two Photographs of the Sailing Ship "Dalgemar."

T. S. Wilson, 543, Lincoln Road, Peterborough. Photograph (Combination) of the Interior of St. Paul's Church, Peterborough, showing New Wood screen and the Rev A. F. Macken.

J. Ambler, Queen's Chambers, 7, Market Street, Manchester. Photograph of Frontage of New Royal Infirmary, Manchester.

D. A. AHUJA.—No further details of the studio have appeared. You might inquire from the Eastman Kodak Co., Rochester, U.S.A. We will bear in mind your suggestion and see if we can act upon it.

PRESS PHOTOGRAPHY.—Some weeks ago I sent a photograph half-plate of a current and stirring event to — for their exclusive use. The photograph was sent about two hours after it was taken, and they reproduced it in their paper. I did not state any price then, but asked them to send what was usual (am I not right in supposing a guinea to be the correct figure?). However, I have received no acknowledgment or reply. What ought I to do in this matter?—CONSTANT READER.

Unless the paper undertook to pay one guinea for the exclusive use you cannot charge this amount. We advise you to send in an account for 10s. 6d. for the use of the photograph in that one issue only of the paper.

PAPER NEGATIVES.—Could you give me information as to the best cheap and quick way of making paper negatives in plain black and white (no half-tones). I have tried several makes of ferro-gallic paper, but cannot get a black nearly opaque enough. Is there any way of intensifying the black of this paper or of changing the blue of ferro-prussiate paper to an opaque colour? Would the process of taking impressions from a dyed plate answer, and if so, where are the dyes to be obtained?—R. W. GRIFFITH.

The sepia process is the best for your purpose; materials from firms such as Marion and Co., 23, Soho Square, W.C. You will need to prepare a negative by contact from the drawing or tracing, and from this make a copy again on the sepia paper or on ordinary ferro-prussiate. A suitable formula for the home preparation of the paper is given in the "Almanac," page 833. The bluish image of the ferro-gallic print cannot be made non-actinic enough, and there is no practicable means of dealing with the ferro-prussiate print. We do not think the print-plate method would work well.

A. D. LEWIS.—We have made inquiries, but cannot hear of the firm.

L. C. CHAPIN (Lincoln, Nebraska).—The process is not yet on the market, but we understand it will be issued shortly.

EMBOSSING PRINTS.—How is the enclosed photograph enamelled and embossed? Is it done by any special machinery or mould made for the purpose?—S. N.

The enamelling is done in the usual way with collodion and gelatine. The embossing is done in an embossing press, which may be had from Jonathan Fallowfield. The method of doing this kind of work was fully described so recently as May 15 last. See page 375 of the number for that date.

H. ADDINGTON.—31, Binfield Road, Clapham, S.W.

G. J. PITT.—Your description, we think, is quite sufficient.

G. E. OVER.—Swan Engraving Company, Charing Cross Road, London, W.C.; Art Reproduction Company, Plough Court, Fetter Lane, E.C.

**TINTING BROMIDE PRINTS.**—Will you kindly give me your advice, through the "B.J.," on miniature colouring? The prints are on glossy bromide paper. (1) Do the prints want any preparing before colouring? If so, the way to prepare them. (2) Which do you think the best colours or tints, and where to obtain them?—**MINIATURE.**

(1) Prints on glossy bromide paper are not at all suitable if high-class miniatures are required. Such prints are usually tinted with transparent coal tar colours, and the paper requires no preparation. (2) Colours specially prepared for this class of work are supplied by all the principal dealers.

**CLEANING ENGRAVINGS.**—I have two engravings stained by mildew. Should be obliged if you could tell me how to remove same without damage to picture. I believe you published a bleaching formula some time back in the "Journal," but have mislaid same.—**ENGRAVING.**

As you have had no experience in cleaning engravings we should, if those you have are valuable, recommend you to put the work in the hands of an expert in restoring engravings. There are several methods of doing the work, and probably the safest in the hands of a novice is to immerse the engravings in a solution of hypochlorite of soda until the stains disappear. A formula for that is given on page 798 of the "Almanac."

**INTERESTED POSTCARD.**—Certainly, a thin piece of celluloid is placed between the wet negative and the (gaslight) paper. Did you not see the article on page 198 of the "B.J." for March 13?

**TROUBLE IN GLAZING PRINTS.**—Will you please help me out of a trouble if you can? When I glaze my prints by squeegeeing them on the ferrotype plates they sometimes come off all right, but at others they stick tight, and can only be got off by tearing the surface. This trouble only arises when I use the — paper, and not when I employ —, which I do not like so well. The way I work is to take the prints out of the last washing water and squeegee them direct upon the plate, after it has been rubbed over with French chalk, or rubbed over with paraffin oil, and then well polished. When the plates are treated either way —'s paper comes off all right, but the other sticks in many instances. I should like to use the —, as I prefer it in use. Can you assist me?—**NEMO.**

It is probable that if you treat the prints on the paper you like best by putting them in a dilute solution of formaline, or alum, and then washing them before they are squeegeed on the plate they will not stick. Probably, also, if the prints were dried and afterwards wetted they would not stick to the plates.

**COPYING DAGUERRETYPE.**—A customer has left with me a Daguerreotype to copy. It is a very good one, but I cannot get anything like a presentable copy from it, do what I will with it. I cannot get a clear and distinct image on the focussing screen; it seems all glare. I have covered up the whole of the camera with the focussing cloth, and stopped out all side light that could possibly cause reflections, but all to no purpose. All appears glare on the ground glass. Can you give me some useful information?—**T. WARREN.**

A Daguerreotype is a very easy picture to copy, and the results, as a rule, are better than those obtained from paper pictures. But you have gone quite the wrong way to work in trying with front light. All direct front light should be cut off, and the picture only illuminated by a strong side light, falling at an angle, say, of 45 deg. Then you will not be troubled with glare. Hold the picture in different positions, as regards light, and see which is best, and then copy it under those conditions.

**COPYRIGHT QUERY.**—Can you please tell me what I can do in the following? The secretary of our cricket club came to me asking what I would charge to photograph the eleven, saying most of the members would require a copy. I told him that I could take the picture (12 x 10) and supply a dozen copies mounted for 30s., and after copies at 2s. each. He said he would not order the dozen, he had done that once before, and that one or two of the team had their copies and he had been unable to get the money for them. He then asked me the price for taking the picture and supplying three copies—one for himself, one for the meeting room, and one for the captain, saying that I could then supply copies direct to them who wanted them, and he expected that all would. I then

agreed to take the group and supply the three copies for 7s. I have only sold one copy, and I now find that copies of the photograph are being sold as postcards all over the district. Can I stop the sale of them?—**FOOTBALL.**

The copyright belongs to the one who paid you for your work. You can do nothing in the matter.

**ON SALE OR RETURN.**—A year or so ago the traveller for a postcard firm called on me soliciting an order for their postcards. I declined to give him, as I did not think they were of subject could sell. He, however, persuaded me to let him leave a card and half, saying that what I did not sell the firm would take and only charge for what were sold. A week or so ago I received from the firm an account for the gross and half pictures the traveller had left. I at once returned those unsold (only a couple of dozen had been disposed of) and asked for the account of those sold, for which I would at once pay. They wrote saying they could not allow for those returned, as they had been through being exposed in the window, or being improperly stored. They are now threatening me with the county court unless account is immediately paid. Are they likely to recover? I will pay at once to save expenses.—**HERTS.**

If the facts be as stated, the firm can recover nothing. If supplied prints that faded in so short a time that was not their fault. Let them sue if they like, but there is no likelihood of their doing so. It is simply a case of "bluff."

**IMPURE WHITES IN VIGNETTES.**—I am sending you herewith a dozen vignettes made on — paper. You will see the margins which should be white are of a degraded or pinkish tint. All the other prints made on the same paper are as good as desired, the whites being quite white, and the same method was used for all. It is only the vignettes that are unsatisfactory, and you will see that they are very unsatisfactory. You enlighten me as to the reason?—**A. L.**

The cause of the tinting is that the toning of the pictures has been done in too strong a light. This is clearly shown in the prints by a faint outline where one print has protected another from the light for a time while it was in the toning bath. I say that the whites in the ordinary prints are pure, but they do not only appear so by contrast with the darker portions. Degradation is the same, except that it is not so manifest in the vignettes—that is, supposing the ordinary prints are under the same conditions as the vignettes.

**PHOTOGRAPHY.**—May I ask you to give us your opinion on the following? A friend and I have had an argument as to whether there is any hand work on the plates from which the German of —'s and —'s photogravures are printed. My friend says that they are free from any retouching; while I can (or think I can) see a large amount of work upon some of them. We ask your opinion on the point.—**J. AND A.**

All the plates are more or less worked upon by hand, a work is done by skilled engravers, who generally spend days on a single plate, and sometimes very much longer. The Germans mentioned make no pretensions that their plates are untouched. Their object is to produce pictures that look as much as possible like veritable mezzotint engravings as possible, and not like photographs at all. Photogravures are mostly reproductions of engravings, and are intended to compete, as such, with engravings.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the test portion of the paper.

## SUMMARY.

easy process to be followed in cases where it is necessary to a figure from one group into another is given on page 511. Enlarging from retouched negatives particular care is necessary in employing a well-diffused illumination but in applying touching in a proper manner. Some notes on these points on page 506.

methods of making reversed negatives direct, either in the or by printing from other negatives, are the subject of notes German worker, Max Frank. (P. 509.)

M. Michell has some practical advice to give on the making es of daguerreotypes and glass positive portraits. (P. 507.) Those who desire to make occasional use of the carbon process es on page 513 may be recommended.

American worker has signified his satisfaction with the reflex as an instrument in the studio. (P. 512.)

apparatus for the mechanical etching of half-tone plates is ed under "Photo-mechanical Notes." (P. 514.)

ulti-colour screen for colour photography figures among of the week. (P. 515.)

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

onpillard, in a lengthy paper on the practice of the Auto-process, recommends the mercury-cyanide intensifier as of al service, and prescribes a weak solution of hypo for use g remover prior to redevelopment. (P. 49.)

lfred Stieglitz, as the result of working with Autochrome nder most trying conditions, advises formalin as a pre- of frilling. (P. 53.)

Roy has recommended sodium hydrosulphite as a means oying the red-sensitiveness of the Autochrome plate after . (P. 63.)

agenous designs of Mr. E. A. Salt, which serve to explain hochrome process, are reproduced on page 55 in such a form y can be copied and coloured for lantern projection.

ufay screen-plate process turns out to be a method of dis- with registration in printing three impressions from a reen. The final screen obtained is one in which the filter- held in plain gelatin. (P. 51.)

or Namias has given a formula for the preparation of non- ochromatic plates by bathing. (P. 52.)

## EX CATHEDRA.

### Irregular Bleaching of Bromides.

At various times we have had questions with regard to the refusal of bromide prints to bleach in solutions such as potassium ferri-cyanide, and bromide, and the peculiar feature in many of these questions has been the fact that the trouble occurred in the case of the lighter tones of the print; that is, in the portions of the image that had received the least exposure. In Dr. W. Scheffer's paper on "Further Researches in the Action of Reducers," a very similar state of things is noted with regard to the persulphate reducer, with which Dr. Scheffer found that "the strongly lighted grains showed a materially greater loss of substance than the less exposed ones." This effect seems to be usual with persulphate, though Farmer's reducer does not give the same result. In the case of the ferri-cyanide and bromide bleacher, the effect seems to be uncertain. As a general rule, the less exposed parts are attacked first, and it is exceptional for them to resist the action of the bleacher. It is, however, clear that in some way the grains of silver in the less exposed parts must differ from those in the strongly exposed portions, else these differential effects could not well take place. It is hard to guess, and very difficult to determine, what the differences are, but it is evident that differences of a somewhat important nature must exist. It may, of course, be that in every grain, large or small, there is a certain more or less uniform quantity of intractable material that will not yield to the reagents. This supposition will explain the effects to a certain extent, but whether it is anything more than a supposition remains to be proved.

### Method in Oil Printing.

When a new process is introduced there is at once an anxious demand for very precise instructions. Generally such instructions are necessary, but the oil process is a peculiar one, and is none too precise in any particular. Several early workers gave very minute descriptions of their own methods of working, but it has become realised that many different methods are possible, and now every prominent worker is probably following methods that are more or less of his own invention. There are many methods of applying the pigment, and one that is perhaps least practised is the simple brushing on of the pigment with sweeping strokes. At times this is very useful, and if print and pigment are both in suitable condition it will give well-contrasted brilliant results. We find that the pigment requires to be exceptionally tacky, and to make it so we prepare the palette half an hour before use. The brush is very lightly charged, but plenty of contrast is soon attained. The effect is perhaps most readily produced when the image has been previously brought up by dabbing with a slightly softer

pigment. As regards palettes, plain glass or porcelain seems most popular, but for our own part we consider any kind of highly polished palette to be unsatisfactory. Bristol board is an excellent substitute for polished glass, but ground glass also has merits. Our most useful palette is a ground glass lantern slide-size cutting shape, fitted with a knob to serve as handle. It is easy to prepare a smooth film of pigment upon this, and it is very readily cleaned after use. We scrape off the pigment with the edge of a piece of glass, and then rub well with a cloth and drop or two of turpentine. As regards the methods of oil and bromoil pigmentation, it is as well to recognise the fact that each process requires different treatment. The bromoil print will not stand so much working upon as the oil print, but at the same time it can be attacked more boldly and with a much more heavily charged brush.

\* \* \*

### Thin Negatives.

Several processes that have been brought out recently are stated by their introducers or advocates to require "thin negatives," but when we are shown the style of negative that is considered most suitable, the quality of "thinness" is not usually the one that impresses us. We were assured at one time that thin negatives were essential for the oil process, and until we knew better we believed it. Trial, however, soon convinced us that fairly strong negatives were the best, and when we had the opportunity of studying the actual negatives used by a most prominent advocate of the "thin" theory we were hardly surprised to find that they were far stronger than any negatives that we were accustomed to make for any kind of printing process whatever. In another process, the so-called "thin" negative that we were advised to imitate proved to have a considerable resemblance to the old order of "soot and whitewash." The shadows were clear glass, while the lights, if not exactly "sooty," were distinctly strong. The fact is that "thinness" or "strength," as applied to negatives, are terms of the vaguest possible nature. Their meaning varies with the worker, and therefore they ought not to be used in instructions that pretend to be precise. They are no more definite than the terms "strong solution" and "weak solution." In the case of solutions, we demand exact formulæ, and in the case of negatives we should have precise descriptions.

\* \* \*

### The Repairs of Bellows and Blinds.

A crack in one of the gussets of a bellows is very easily repaired with indiarubber, and a camera which, from age or improper storage, has suffered in this way is quickly put into working condition again. A piece of thin indiarubber cloth—that sold at the rubber shops under the name of thin "nursery sheeting" is best for the present purpose—is cut a little larger than the portion to be repaired. This and the part to be repaired are smeared over, with the finger, somewhat thickly with rubber solution. When the solvents of the rubber have evaporated, and not before, the two rubbered surfaces are brought into contact and pressed together firmly with some hard surface—say the thumb-nail—when they will adhere with great tenacity. It may be well to mention that if the patch is misplaced in the first instance it is of no use to attempt to regulate it afterwards, or apply fresh cement: the patch should be taken quite off and the rubber cleaned away, both from the patch and the place to which it is to be applied. This is easily done by gently rolling it off with the ball of a finger, when it will come off cleanly. Fresh solution can then be applied. Any of the cement that may be outside the patch can be rolled off with the finger, so as to leave the work neat and clean. In the case of the repair of roller-blind shutters, the nursery sheeting may be too thick to permit of the blind working freely. At

most of the better-class mackintosh shops indiarubber, coated silk is to be had. This is exceedingly thin, a well suited for the thinnest roller blind. It should be to a round or oval shape, so as to avoid sharp corners and if neatly applied will in no way interfere with the working of the blind.

\* \* \*

### Rubber as an Adhesive in Combination Printing.

Writing of the above use of rubber to mind the special usefulness of rubber as an adhesive for temporarily affixing masks to the negative. This is usually done with gum or other aqueous cement, but if at a future time the negative is required for other purposes, the mask can seldom be removed without leaving marks or stains where the adhesive was applied. With rubber used as the adhesive, however, the mask can at any time—even months afterwards—be pulled off, and any adhering rubber rolled off, and then the negative be left in perfect condition. In some cases of double printing on P.O. it is convenient to hold the mask firmly in position while printing. This, of course, is impossible with any aqueous cement, but with rubber solution it is quite practicable. A few touches of the solution are put on the negative, the paper laid in position, when it will adhere. After printing, the paper is pulled off, and any rubber sticking to it rolled off with the finger. The print can then be toned, and no mark due to the cement will show in the finished picture. Again, in double printing in the camera process, one of the methods is to secure a mask to the tissue with dabs of rubber solution. After printing, the mask, which will serve for many prints, is removed, the dabs of rubber rolled off, when the tissue will develop just as if it had not been touched by the cement.

—♦—

### THE ENLARGING OF RETOUCHED NEGATIVES.

FROM time to time we receive inquiries as to difficulties arising in the enlargement of negatives which have been retouched, and the matter seems to be one of such general interest as to demand some detailed consideration. The usual complaint is that the retouching shows unduly in the enlargement, and the matter thus naturally divides itself into two sections—viz., defects in the retouching and mistakes in the process of enlarging.

The work of retouching may be subdivided into more usual retouching with the pencil and retouching which is aided by the knife or scraper. There are to begin with, various ideas as to the quality of retouching and a retouching which would satisfy a worker perfect in the original size might appear to him quite unsatisfactory on an enlargement even though that were the most possible. The ideal retouching is that which does not show as retouching, but the effect of which only is visible. Such work is done by a combination of artistic skill and technical ability which selects the suitable retouching medium, applies it in proper quantity, employs the degree of hardness of lead and the exact pressure required. It is fairly safe to say that nine out of ten professional portraits are retouched in such a way that though the contact print in platinotype may scarcely show any trace of pencilling, the enlargement will require "fading up" before it is satisfactory from the commercial point of view. Some retouching mediums are to blame for the effect of the finished work. The medium may be too tacky, and thus drag too much lead from the suitably soft pencil. If a hard pencil is then employed the touch is wiry or scratchy, the individual lines or touches being more or less apparent. The mediums, on the other hand, are friable or brittle

pressure of the pencil breaks up the thin and hard film. It is obtained a suitable medium and ascertained how much of it is necessary to apply to the film, the quantity being, of course, with the nature and extent of the work done, the choice of pencil comes next. A safe rule is to employ as soft a pencil and as light a touch as possible, consistent with a secure application of the lead. Any grasp and any hard pressure are almost sure to result in a mark which shows as a mark and the consequent action of photographic texture.

Work on the negative is certain to show much more prominently when enlarged than careful pencil work. The key is always to scratchiness, and to avoid this the edge of the scraper blade should not be too small. A scraper with a long radius gives an edge which will take off only broad shaving of film, while a short radius curve will be practically a scratch. Some making good the pencil is always necessary, and here the finest and hardest pencil is very useful.

Coming now to the enlarging of the properly retouched negative, we may make the broad and, of course, obvious point that all marks on the negative—that is, places where the opacity has been increased by the application of the scraper or decreased by the use of the scraper, must inevitably be enlarged, whatever the optical and illuminating arrangements. We are assuming, of course, that the enlargement is sharply focussed. If a direct light is used, however, much more than this will show. Any streakiness, such as the marks of the cloth or finger application of the retouching medium, any finger produced by resting the hand on the negative during the operation, or even a slightly greasy finger mark on the side of the negative, will show distinctly on the

enlarged print. An abrasion of the retouching medium, if that is rather too hard and brittle and the pencil is hard, will also show prominently, the effect being that of a blacker line on the negative or a whiter line on the enlargement than was intended. We may safely say, therefore, that under no circumstances should a negative be enlarged with a raw light unless it is absolutely untouched and free from even the most minute defects, both as to film and glass. Such negatives are rarely met with, and, of course, the professional portrait is excluded from such a class. The light used must be diffused, and it is not only necessary to diffuse the light passing through the negative, but to start further back still, and by means of a sheet of finely ground glass to diffuse the light before it passes through the condenser. If the ground glass is placed between the negative and the condenser, it must be fairly near to the negative, for the latter is always placed as closely as possible to the condenser. In this position the effect of diffusion is very slight, and there is, if a rather small stop is used in the projection lens, some risk of getting the grain of the ground glass in the enlargement. By placing the ground glass between the lamp and the condenser a perfectly diffused illumination is obtained, and no markings on the negative will be apparent on the enlargement except what may be seen when looking through the negative at a sheet of white paper well illuminated by daylight.

Should it be necessary at any time to enlarge a negative the retouching of which is scratchy, it may be an advantage to put the picture just slightly out of focus. The effect will not be one of general unsharpness or pronounced fuzziness, while the fine scratchy lines will be softened and made less conspicuous.

## ON COPYING FADED AND DETERIORATED PICTURES.

I.

### A Convenient Copying Device.

One of the very profitable parts of a professional photographer's business is the copying of old photographs of different kinds. Sometimes happens that some old and faded portrait is sent to him from which a reproduction, or enlargement, is made, as it may be the only representation in existence of a deceased and dear friend. More often than not, such a picture is in a very faded condition. I have had many old photographs, taken on the beach, through my hands, and there have been other and better photographs of the same person in existence, these have been preferred, simply because they are considered to be the best likeness. This is not only the case with such pictures, because the sitters have been taken "just for the fun of the thing," for, perhaps, a small fee; or so; hence there was no anxiety that the picture should turn out to be good, as there sometimes is when a subscription figure is paid for one taken in a studio. I knew a professional photographer who made a specialty of producing enlargements from old and faded photographs. These were vignettes with the objectionable parts thus taken out. They were then highly finished in monochrome, and my friend sent for his work as many guineas as the original picture cost. But his results were excellent, and conveyed whatever that the originals were common glass positives, or types, taken by a beach photographer for a few pence. Now photographers, when they have the kind of pictures referred to brought them to reproduce, look upon them as the light of a nuisance than as a source of good profit. With good business tact, they might frequently be made a very profitable line.

In this article I propose to say something on the subject of copying generally, and shall deal, *seriatim*, with the different types of pictures which come into photographers' hands. In some studios there is no convenient arrangement for copying photographs, and, as a result, the picture is pinned on a wall of the studio, the camera simply placed in front of it, and a copy made. Possibly, when all is satisfactorily arranged, a sitter arrives, and the copying has at once to be put aside. It is for such reasons as this that copying is often voted a bore by many. This trouble may be quite avoided, however, by having a proper copying board such as any one can easily make for himself; if not, any local carpenter will do the needful for him for a mere trifle. It need only be of small size, for the majority of this class of work seldom exceeds the half-plate size. All that is required is a stout board, about five feet long and an inch or so wider than the base of the camera employed, which may be a whole-plate or a half-plate. Along each side a thin lath is bradded, between which the camera slides. At one end is fixed a small drawing board, at right angles to the base, upon which is fastened the picture to be copied. For convenience in storing when out of use, the drawing board may be hinged so as to fall flat, being held in position, in use, by a couple of studs. The convenience of this simple piece of apparatus is that there is never any question as to whether the picture on the copying board is at right angles to the camera, so that all that has to be done is to move the camera backward or forward to get the size required. This arrangement may be secured on the top of the camera stand by an ordinary thumb-screw, or held on it by

a screw clamp. It may even be laid on a table or any other support, and can be turned or twisted about to any angle, so as to obtain a suitable lighting, a thing that is most important in copying deteriorated pictures, as this can be done without fear of disturbing the relative positions of the camera and the picture. Furthermore, should a sitter arrive, or the operator be called off, the whole can be lifted off and put aside without interfering with the arrangement.

#### Copying Daguerreotypes.

It may be as well to commence now with daguerreotypes. A daguerreotype, it may be said, is a picture taken on a silvered copper plate. It may seem quite superfluous to many to mention that, but I have, more than once, known old collodion glass positives being mistaken for daguerreotypes. Not infrequently, when one of these pictures is brought to be copied, it is more or less "faded"—that is, the silvered surface has become tarnished, and to a considerable extent the image has become hidden beneath it. These pictures can be "restored" by judicious treatment with a solution of cyanide of potassium, but the work is a ticklish one in the hands of those who are not familiar with the working of the daguerreotype process. Therefore I would suggest, when a daguerreotype is received in a tarnished condition, that it either be copied as it is, and the best possible made of it, or that it be placed in the hands of an expert: for if a novice attempts to do the work for the first time, the picture may be irretrievably ruined. No one should try his hand on a highly prized picture without previously experimenting on three or four of no value.

We shall assume, however, that the daguerreotype has not "faded," or that the best has to be made of it in its present state. I have read in the "journals," with, in some instances, amusement, most elaborate directions given for copying daguerreotypes, which the writers seem to think a most difficult thing to do. Personally, I look upon these pictures as being about the easiest of old photographs to copy, and the results they yield, if the picture is a good specimen of the process, look more like a photograph from life than a reproduction from another. Every one knows that a daguerreotype can only be seen in perfection in certain lights, and that is when they fall upon it at an angle. Therefore it follows that in copying the picture it should be lighted in a similar manner. In the first place, the picture must be taken out of the case and the covering glass, which is cemented to it with paper, removed. In doing this it must be handled with the greatest care, for although the daguerreotype is one of the most permanent of all silver pictures, its surface is so exceedingly delicate that the slightest touch upon it may cause permanent injury. If there is any dust on the plate, it should be removed with a bellows. A camel-hair brush, unless very lightly used, will produce very fine scratches on some of these pictures. With others it may be lightly used, as these pictures are not all alike in this respect.

#### Lighting Daguerreotypes.

The next thing is to fix the picture on the copying board. The light that should be employed in copying a daguerreotype is a strong side one, falling upon it almost at a right angle. All strong front light must be stopped off. On very closely examining a daguerreotype it will often be seen that there are some very faint lines, always in one direction, left from the "buffing," that is, the final polishing of the plate. When these can be detected the picture should be fixed on the copying board so that the light falls parallel with them, then they will not show in the copy, if thus arranged. About the best place to copy these pictures is an ordinary room with the originals placed at the side of the window. There is then no trouble with reflections. Similar conditions can, of course, be arranged in the studio. In lighting daguerreotypes it should be kept in mind that the angle of reflection equals the angle of incidence. Therefore, if the light falls on the picture, say, by way of example, at an

angle of 45 deg., the reflections from it will be at a similar angle and consequently quite away from the lens, so that we get a brilliant image in the camera; whereas, if it were lit with front light, the reflections from it would be towards the lens, with the result that there would be no brilliant and distinct image obtained.

#### The Care of Daguerreotypes.

For the negative any ordinary plate will suffice, but the slow ones, as a rule, yield the best results. When the negative has been secured the picture should at once be cemented to a cover glass as it originally was, and then returned to the camera to protect it from the atmosphere. In nine cases out of ten when a daguerreotype has faded, it will be found that, at the time or other, it has been taken out of its case for copying, not papered up again by the one who copied it. Hence, if one had access to it, the effect being most manifest round the edges.

#### Copying Glass Positives.

We will now consider the copying of another type of photograph, namely, glass positives. Many of these brought for copying may, possibly, be as good as when they were first taken, perhaps over forty years ago, that is, if they were properly cared for at the time, and backed up with either black velvet or a coating of good black varnish on the back of the plate. We call this "good" black varnish because some of that sold in the days of the positive collodion process was prone, after a while, to crack and split off the glass. That, however, is of no moment, as the varnish can easily be scraped off and replaced, when the picture will be just the same as it was at first. Sometimes, however, the black varnish was applied to the collodion surface so as to obtain a non-reversed picture, and also to save two varnishings. But when that was done, the whites of the pictures, as can readily be understood, were so pure as when the black was applied to the glass side, and, supposing that the black varnish was applied to the collodion side and has become cracked, we have a ticklish thing to deal with in the cracking of the varnish the collodion film, bearing the image, has likewise cracked, and possibly is splitting away from the glass. Great care has therefore to be taken that the picture does not get actually disturbed in handling. When a picture is in a bad condition it should be backed up with black velvet and, if made in the usual way, the negative being touched up afterwards. Sometimes, however, such pictures can be, temporarily at least, repaired in the following way:—The picture is taken out of its case, or frame, and exposed for some time—an hour or two, perhaps more—to the vapour of benzole. This is done by placing it, face upward, on a small block of wood in a dish, then pouring in benzole till it nearly reaches the picture, and then covering the dish with a plate of glass to prevent the evaporation of the benzole. By this treatment the vapour of benzole usually softens or semi-dissolves the bitumen varnish, and the fissures become healed up; also the collodion film goes back to the glass. When this occurs the picture should at once be copied. Then if a good black varnish is applied, a permanent repair may often be effected. The treatment, however, is not always successful, as a good picture will depend upon whether the picture has been much exposed to light, as the continued action of that would be to render the bitumen insoluble in benzole.

#### Making the Best of a Poor Positive.

The copying of a good glass positive in good condition is a simple work, and needs no comment. But very frequently the originals are just the reverse, being flat and lacking in contrast. We shall here assume that the picture has been varnished on the collodion side with a transparent varnish, the back with black varnish, or backed up with black velvet. From a picture of this description it is possible to obtain a brilliant negative in the ordinary way of copying. In such a case the best procedure is to remove the black

at the picture as a negative. It may be as well here to mention, for the benefit of those who are not familiar with the process, that a glass positive is, practically, an under- and under-developed negative, and the flatness sometimes seen in these pictures is usually due to over-exposure and development. Indeed, the worse some portraits seem as the better they show as negatives. From them transparencies can be made on dry plates by contact printing without injury. In many cases, however, glass positives, partly when they are the work of itinerant photographers, are varnished at all, and the silver surface has become dulled or stained. In this case, if the picture were copied in the usual way, the stains would show strongly in the negative. The collodion film in these cases has become decomposed, and is in character, with age, so that it is impossible to deal with the picture in the way just referred to. The film is probably so tender that it can scarcely be touched without suffering. Some, indeed, are almost as delicate to handle as wetotypes. If an attempt be made to varnish a positive of this kind, the probability is that the whole of the film will be dissolved by the varnish. Very frequently the varnish on positives may show very strongly when reflected light, but will show but little, or not at all, when by transmitted light. When this is so, good reproductions can always be obtained by copying them in the camera

by transmitted light, getting a transparency from which a negative can be made by contact printing.

Another way of dealing with pictures of this kind is as follows:—An enlargement is made direct in the enlarging camera on bromide paper, using the picture as a negative. This, being thin, is well suited for bromide paper. The enlargement is then worked up in monochrome and afterwards copied on a reduced scale. Supposing, say, the original is a quarter-plate or smaller size, the enlargement is made of the whole-plate, or 10 by 8, size. Then, after working it up it is copied to, say, cabinet size. When this system is adopted a good order for cabinets frequently follows, as the customer has no idea that such a good result could be obtained from such an unpromising original. Should an enlargement from the small original be ordered in the first instance, it may be made the full size direct, and then finished. From the finished enlargement reductions can be made to any size, and in this way further orders obtained.

I, like many others who have made a specialty of this class of work, have had many very profitable orders for copies and enlargements of wretchedly old and faded photographs, and I am surprised that so many in the profession seem to overlook this line of business. In a future article I propose to deal with the copying of other kinds of deteriorated photographs—paper prints in particular.

WM. MICHELL.

## METHODS OF PREPARING REVERSED NEGATIVES DIRECT.

For many purposes of enlarging and printing the making of one negative from another by a quick and certain method is a desideratum, as it is also in the preparation of transparencies for projection. The latter presents a more difficult problem than the former owing to the necessity of having perfectly clear high-lights, and therefore the following methods, which are given in recent issues of "Photographische Korrespondenz," whilst no doubt expressing the practical success of the writer from his point of view of preparing reversed negatives, can scarcely be recommended with the same confidence to lecturers and students in need of a quick and direct method of preparing a lantern slide from a drawing or diagram without the intervention of a negative. Of the processes named by Herr Frank, probably the Pinatype or dusting-on method would be the most satisfactory for this latter purpose could sufficient rapidity be, at the same time, obtained.—Eds. "B.J."]

It may be taken of the reversal of the image on a dry plate making one negative directly from another. With an exposure of several hundreds to several thousands the normal a negative is obtained instead of a positive transparency, but it is not every make of plate is adapted to this process. A plate which "works hard" is better than one which is soft. In the case of fine-grain plates reversal takes place so easily as in those of coarser grain. The result, also, should be one tending to contrasty and clear. Hydroquinone, pyro, adurol, and glycine are among the best reagents, and attention is needed in pushing development further than would be usually done, since the negative is somewhat less brilliantly than would be thought desirable appearance. Developing solution which has been used once or twice is preferable to freshly made, which readily gives soft results, over-exposure of negatives. It will be found that the image comes up quickly and with too much detail if the exposure has been overdone, the behaviour of the plates being exactly the same as that which follows ordinary exposure in the camera. The negative and the dry plate are pressed well in contact, film in an ordinary printing frame, and exposed either to light or daylight. In the case of the latter an exposure of half to three minutes to diffused light from a window taken as an average, depending on the distance of the plate and the speed of the plate.

Development the image appears first as a weak positive,

which disappears again in the developer, being replaced by a negative image. The developed plates are then fixed in an acid bath. The method of preparation naturally gives a reversed duplicate negative. If one correct as regards right and left is required the process must be repeated, using the reversed negative first made as the starting point. Films will, of course, obviate this, as printing can be done from either side; whilst, if the purpose of the reversed negative is enlargement, reversal is, of course, no objection. A good deal can be done in the process in the way of preparing an improved negative, the hardness or softness of the original can be greatly modified, and the process, with some practice, is sufficiently certain for regular work, especially when a constant artificial light is used.

### The Dusting-on Process.

The dusting-on process is well known as a means of preparing one negative from another, and it is only necessary to mention a formula, that of Bruno Meyer, which can be used for the purpose:—

A. Gum Arabic .....	8 gms. ....	$\frac{1}{4}$ oz.
Glucose .....	20 " ....	310 grs.
Honey, clear .....	4 " ....	60 "
Alcohol, 96 per cent. ....	3 " ....	50 minims.
Glycerine .....	2 to 5 drops	2 to 5 drops
Distilled water .....	20 ccs. ....	$\frac{1}{2}$ oz.-100 minims
B. Ammonium bichromate ...	10 gms. ....	1 oz.
Water .....	100 ccs. ....	10 oz.

One part of A is mixed with two parts of B and three parts of

distilled water added, the whole mixture being filtered until perfectly clear. Glass plates coated with this mixture are exposed under the negative until a faint brownish image is produced, and are then, on removal from the frame, allowed to remain for some time in a dark, but rather moist, place, when the image is brought up by dusting over finely powdered graphite with a soft brush. This "development" process is done by weak daylight or lamplight.

In this process under-exposure gives too hard results, over-exposure too flat.

#### Pinatype and Another Method.

Of other methods depending upon the property of bichromated gelatine the two following are of service in practice. The first is a modification of the well-known pinatype process. A glass plate is carefully cleaned and coated with  $\frac{1}{2}$  per cent. solution of potassium silicate, and whilst still moist with a warm solution of 2 per cent. gelatine (the hard collotype gelatine). It is dried and then sensitised in a cool 2 to 5 per cent. solution of potassium or ammonium bichromate. Sensitising, which is done by lamplight or weak daylight, should last about five minutes, and the plate should then be dried in a dark room or in a drying-box. Care should be taken that no drops of liquid remain on the film. The careful use of a pad of soft linen will remove them before drying. If they are left the negative will show patches of greater density. Exposure is done as usual in the printing frame, and its progress can be judged by the positive print to be seen at the back of the glass, of brownish colour on a yellow ground. This should be examined by the yellow light of the dark-room as, as soon as details are visible in the highest lights, the plate should be washed, also by yellow light, until the positive image has disappeared. The plate is then freed from bichromate in a 2 per cent. solution of potass metabisulphite, and then thoroughly washed.

It is now laid in a 1 per cent. solution of the pinatype "platinum black M" of Meister Lucius and Brüning, which penetrates the film only in the parts unexposed to light. A final rinse from the dye solution completes the process, in regard to which it should be understood that the coloured gelatine film is the more intense the less exposure is given. By modifying the sensitising bath the character of the negative can be altered. For flat and weak originals a weak bath, 1 to 2 per cent., should be used, whilst for stronger and harder negatives the strength of the bichromate should be 5 per cent. The time of exposure and choice among the various dyes suitable for the purpose also allows of the reproduced negative being modified in character. The negatives made in this way show very little grain, and are to be recommended for enlargements.

A similar method is that of Bigny. A gelatine dry plate of medium speed is bathed in a 2 to 5 per cent. bichromate solution, dried, printed, and washed in the manner just described. The bichromate is also removed with potass metabisulphite, and after a thorough washing the plate is treated, in diffused daylight, with a strong developer, such as ferrous oxalate, metol, glycin, or rodinal. The exposed gelatine is thus rendered insoluble according to the action of the light. The plate can be exposed for about a second to the daylight, but the glass side should be covered. It is then fully developed in the dark-room, and then washed, fixed in an acid bath, and again thoroughly washed. In this process also, modification, as described for the pinatype method, can be made in the reproduction.

The foregoing methods allow of the making of a duplicate negative only of the same size as the original, that is to say, in the printing frame, and the negative is also reversed as regards right and left. A method, which allows of the use of the camera, whereby enlargement or reduction can be carried out, and an

unreversed duplicate also obtained, has obviously many in practical work. The reversal method first given in article may be used, but is not recommended, as the exposure frequently altogether too long. The following chemical reversal methods are more practical. The first is that of M. Balagny in which the image is first developed, dissolved from the fixed plate with bichromate and acid, and the plate again developed.

A plate of "ordinary" sensitiveness is used, and is given exposure of about twice that which would be considered necessary for an ordinary exposure. It is then developed in—

A. Distilled water .....	1,000 ccs. ....	35 oz
Sodium sulphite .....	250 gms. ....	8½ c
Hydroquinone .....	20 „ ....	310 gr
B. Water .....	1,000 ccs. ....	35 oz
Sodium carbonate .....	250 gms. ....	8½ c

The developer is prepared from these two stock solutions taking A three parts, water three parts; B two parts, and a bromide solution 10 per cent. one part. When using newspaper instead of plates two parts of 90 per cent. alcohol should be added. The image appears slowly in this solution, and is allowed to act until the positive image, visible from the back of the plate, is quite black.

Too short development will lead to a flat and foggy negative. The plate is then carefully washed and laid, glass side down, on an ebonite dish or on other black surface. It is exposed then to twenty seconds to diffused daylight, whereupon the previously greenish high-lights become whitish-grey. In order to avoid fog at the edges the plate should be covered with opaque edging. It is afterwards placed by the dark-room operator in the following bath:—

Potass bichromate .....	6 gms. ....	93 grs.
Nitric acid .....	5 ccs. ....	85 minims.
Distilled water .....	250 ccs. ....	8½ oz.

In it the black image disappears. After thorough washing the plate is placed in the developer already used, and the negative image brought to full density. It may be well to give the negative five minutes in a 5 per cent. solution of chrome alum, afterwards washing. It is then fixed, and the hypo finally run in running water. Instead of the short exposure of the negative to daylight and the use of the bichromate in the dark-room, a bichromate solution of half-strength may be used in daylight. Thorough washing at the various stages is essential to success of this process.

#### Reversal by Persulphate.

Ammonium persulphate may also be used as a reversing agent. In this case also the exposure is made in the camera on to a dry plate of medium speed, which is then developed twice the usual time, thoroughly rinsed, and the alkali completely removed by adding one or two drops of sodium acid to the washing water. The positive plate is then, in a 10 per cent. ammonium persulphate solution, which covers the plate to the depth of half to three-quarters of an inch. The plate in this solution is allowed to remain for 10 to 20 minutes to diffused daylight until the image has completely disappeared when examined by transmitted light. The plate is then thoroughly rinsed, placed for one to two minutes in a 1 per cent. sodium sulphite solution, and redeveloped in any strong developer. It is finally given a short rinse, fixed, and then washed.

MAX F.

\* Reference may also be made to the formula for the Balagny method mentioned by Mr. C. R. M. Farr in "B.J.," November 8, 1907, page 846. The method also obtained the approval of M. Jos. Maes, "B.J.," March 216.

## REPLACING MOVED FIGURES IN GROUPS.

There is the professional photographer who has not been at all annoyed, after exposing a number of plates on a group of five or six figures, to find, when proofs are submitted, that they are rejected because one or more of the party have moved, or, possibly, one or two shown unsatisfactory expressions. This arises, notwithstanding that the most sensitive plates and the quickest-working lens have been employed. Either a re-sitting has to be given, or a customer will go away dissatisfied. If re-sittings are given, it not infrequently happens that the new pictures are no more satisfactory than those first taken. Now, if the faulty portraits could be removed from the general best picture and replaced by one from one of the others, the group would be considered satisfactory and a re-sitting avoided. It goes without saying that the only way this can be done is by double printing, an operation which is regarded by many present-day printers as being very difficult to carry out, but, in reality, a very simple matter.

In taking groups of children few photographers rely upon a single plate. A couple or more are usually exposed, and proofs are sent only the best submitted to the customer. In taking the negatives, the positions and lighting of the figures are not altered between the exposures, so that all the pictures are more or less alike except for possible movements. Even if the pictures are not exactly alike, it makes but little difference in the process of combination printing now to be described.

### A Simple Method of Masking.

We will suppose, by way of illustration, that in a group of persons, one of them, through movement, or bad expression, is to be replaced by another from one of the other negatives. The procedure is as follows:—One of the negatives, that in which the portrait offending is considered to be most satisfactory, is taken, and all the other figures blocked out with black ink. Or a print from the entire negative may be made on P.P., and this one figure neatly cut out. This, after the paper has been blackened by exposure to light, may be fixed as a mask on the negative with a few touches of indiarubber solution, which answers quite as well as black varnish, and has the advantage that the mask can at any time be removed. A print is then made from the masked negative. For convenience in printing, it should be on paper a little larger than the negative. The paper used should be either albumen or collodio-chloride, not gelatine P.O.P., for a reason to be presently given. The single figure will, of course, be on a piece of quite white paper. When printed the figure is painted neatly over with a matt black colour—gamboge is as good as any. This is a work which takes a minute or so, and requires no special skill. When the colour is dry the print is ready for the second printing. All that has to be done is simply to place the paper on the

generally approved negative, arranging the already printed figure so that it occupies its proper position in the group. There is no difficulty in doing this, as the gamboge being a transparent colour, it can easily be done by looking through the negative. The second printing is then done as usual. The toning and fixing is done in the ordinary way. In the washing out of the free nitrate of silver previous to toning, the gamboge is also washed away, and the toning afterwards proceeds just as well as if the print had not been subjected to any special treatment.

It was mentioned just now that only albumen or C.C. paper should be used for this work, and it may be as well to explain the reason. With either of these papers the colouring medium (gamboge) is not absorbed in the surface coating of the paper. In the case of a paper such as gelatine P.O.P., which is freely absorbent of water, the washing out of the free silver would not suffice to remove the colour, and a mark would show more or less in the finished picture. It will be seen that by this simple method of procedure double printing of this kind is a very simple affair, and can be successfully carried out by any one who may be quite a novice in this class of work.

### A Saver of Re-sittings.

With group pictures of the kind we are at present supposed to have in view, if it is seen that one member of the group has moved, it is good policy for the photographer to replace the moved figure by a still one from one of the other negatives before showing the proofs to the customer. In these circumstances the re-taking of the group, with the chances of movements in the new pictures, may usually be avoided. It will be recognised that by this simple system of double printing only one negative has to be masked; in other methods both have to be, and accurate registration in the two printings becomes very important. By the method just described this extreme accuracy in the two printings is not quite so imperative.

It is quite an easy affair, by the above method, to introduce an extra figure that was not present when the group was taken. This is done as follows:—The portrait to be introduced is photographed of a size to correspond with the others in the group, care, of course, being taken that the lighting and the density of the negative are similar to the others. The background of this negative, which may be on a smaller plate than that of the group, is blocked out. The figure is then printed—the other portions of the paper being protected from light—so that we get the figure only on quite white paper. The figure is then painted over, and the printing from the group negative done; the printed figure, of course, being placed on the negative in the position it is to occupy in the finished picture.

H. V. TODD.

J. JONATHAN FALLOWFIELD, dealer in "Taquta" cameras and photographic requisites, can hardly have repressed a smile when he read the following in a Harmsworth evening paper, quoting *Manchester Guardian*:—

"Variation on the ordinary street photographer—who, by the way, is to be dying out—was met with in Manchester the other day. He had on a tripod a small camera in the shape of a toy cannon, the barrel of which was pointed at the sitter, or rather stander. The process was automatic. Under the camera was a small tank containing the developer.

The photographer pressed a bulb—the exposure was instantaneous and then pulled a rod, which caused the plate to drop into the developing bath, from which it was drawn a few minutes later to produce a photograph, about the size and shape of a penny—price sixpence, or, in a brooch, sixpence.

"The positive" was produced directly in the camera without the intervention of a "negative." After being washed in water it was

ready for the customer, all but the drying. A photograph turned out a little after six in the evening in a town street—conditions under which snapshot photography with an ordinary camera and fast dry-plates would have been impossible—was cloudy in parts, but a quite complete and recognisable portrait.

Presumably the process was some form of the old "positive collodion" process, but this would hardly work with an instantaneous exposure, unless there have been improvements. The owner of the instrument declared that it was "from Chicago." (The Chicago Ferrotype Co.)

A SUICIDE.—On Saturday in last week a well-dressed man, apparently about thirty-five years of age, was found lying insensible on the grass in Hyde Park, with a bottle which had contained poison by his side. He died two hours later without having recovered consciousness. The man's clothing was found to contain cards bearing the name of A. H. Lloyd, photographer, Weymouth.

## THE PROFESSIONAL PHOTOGRAPHER AND THE REFLEX CAMERA.

[The advantages of a reflex camera, not only out of doors but in the studio, have been strongly emphasised in our columns of late particularly by Mr. Gordon Chase, now of Muswell Hill, by whom very effective use of a reflex has been made in portraiture. Still we may quote some recent notes by Mr. C. H. Claudy in "Wilson's Photographic Magazine," wherein commendation of this type of camera is given by a practical professional photographer.—Eds. "B.J."]

In case there are some whose attention has been so strictly confined to the gallery end of the business that they have no knowledge of a mirror camera, let it be said that a mirror camera is one which has a horizontal ground glass, and a mirror, set at an angle, which reflects the image formed by the lens to this horizontal ground glass. This ground glass is the same distance, optically, from the lens that the focal plane is. Over the ground glass is erected a hood, through which the operator looks. The mirror acts as an erector for the image, turning it right side up. The distances being the same to ground glass and focal plane, the image, as viewed through the hood, is the same size as the finished picture.

When a picture is to be taken, the operator focusses the lens by turning a convenient milled head, watching the full-size, right-side-up image on the ground glass, through the hood. When it is as he wants it, he presses a button. This button releases the inclined mirror, which flies out of the way, closing off the ground glass and making a light-tight joint. When it is seated, and not before, it releases the previously set focal-plane shutter. The "lag" in time between pressing the button and the release of the shutter is a very small fraction of a second—possibly a twenty-fifth, so the picture is made just as it is seen on the ground glass.

This, in effect, is the reflecting type of camera. On this side of the water the most prominent example is the Graflex. The advantages of a focal-plane shutter have already been discussed, so nothing further need be said on that head, except to remark that all that applies to a focal-plane shutter in any camera applies to it in a reflecting instrument.

### Tests of a Reflex Camera.

Now, it should not need much demonstration to see that for any subject which is in motion, or liable to move, an instrument which allows focussing to be done to within one twenty-fifth of a second of making the exposure puts a great power in the hands of the photographer. Two men making pictures of a dog. As fast as the one gets his tripod instrument set up, focussed, slide drawn, and is ready to press the bulb, our canine friend gets up and lies down three feet nearer the camera. Or he moves out of the line of vision—and in either case, re-focussing and the same with the "fo" left out becomes essential. The other man, with his hand camera, merely adjusts the focus while looking at the dog, and presses the button as soon as his dogship assumes the position desired. If the position is but momentary, it is long enough. I remember some experiences with sheep, than which no more nervous and un-stand-stillable animal exists, in which a Graflex produced picture after picture that set the owner frantic with delight, while a stand camera failed utterly in everything except frightening the timid animals out of what little sense they were provided with in the first place.

When it comes to photographing a jumping horse, the stand camera is all right if you know which five-barred gate he is going over, and can get exactly where you want and focus on the gate in the first place. But otherwise, if you are not absolutely certain that the horse is going to occupy a given position in the atmosphere at the time you want to make the picture, you are necessarily quite helpless without a reflecting camera.

And as for children! If you do child work in the studio, you have no need of any one to write an exposé of your troubles. But if you have tried children in natural surroundings with a stand camera, you may be glad to have some one voice the complaint every one makes of such pictures: If without motion, they are stiff and unnatural—the sitters knew they were being photographed; if natural in pose and expression, they are either out of position or show movement. With the reflecting camera indoors it is frequently possible to photograph the squirming baby, because of both

the ability to focus a squirm and get enough light on it—combination of mirror and focal-plane shutter. Outdoors you can do about with playing children and picture them, time after time, while they are unconscious of your work. The result is the kind of picture that sells.

### The Business Power of a Reflex.

Now, I would not pretend for a moment that just because you expend good money for a reflecting camera you are bound to be rich, or that you will have trouble dodging the dollars and finding time to write up your order-book. But if your town is like other towns, and if your customers are of the same kind as most people's customers, you will find that just as your equipment provides for varying and various kinds of work, so you will have various varying kinds of work to do.

You will not experience any particular difficulty in learning to manage a reflecting camera; but you will have to revise your estimate of outdoor timing, since focal-plane exposures are faster, for light, than other kinds of shutters. You will also have to learn to allow for the tiny fraction of a second of "lag" between pressing the button and the release of the shutter, but only in very fast movement. You will have to learn to allow speeds for various degrees of movement, at different distances from the camera and at different angles—a matter of small difficulty from tables provided for the purpose.

You will not have to learn the convenience of the instrument. Once you have used it you will want to take it straight to your studio and use it there; nor, if you have a fast lens and a good light, is there any reason why you cannot use it there. In fact, the use of the reflecting camera in the studio for baby and animal work is one of its great recommendations to the professional, since by its aid he can obtain pictures utterly impossible or at least, extremely difficult—with any camera in which a measurable interval of time must expire between focussing and the release of the shutter.

You will wonder, perhaps, at my saying that snapshots in the studio can be made with the reflecting camera held in your hand, but as it is not only feasible, but perfectly easy, to make such snapshots with such a camera in an ordinary light front room, there should be no difficulty whatever under the light.

Of course, you cannot screen down your light and get Rembrandt effects and expect to use a mirror camera at even its slowest speeds, and with the fastest lens and get fully timed negatives. But with an uncurtained light and a good lens, and a bright day, you can set the focal-plane at one-tenth to one-twenty-fifth of a second, see what you are doing on the ground glass, press the button when you think what pleases you, and be sure—particularly if you use the tail of a well-graded, fully timed, properly developed negative.

When you think of the ability this puts in your hands, the facility with which you can walk all around not only a baby, but a grown-up sitter, observing any change of expression and alteration of expression, with the ability to take what you see instant it appears and before it is gone in another change, you realise what the mirror camera does for you.

That it is not more used is nothing against the instrument, an argument against the ignorance of its possibilities which generally obtains among a large proportion of the profession.

Yes, they cost money. The makers don't give them away. A fine lens costs money. And the spending of it in a too expensive appliance of this kind, which can be made to pay dividends in many different ways, is one of the surest assurances that the maker you want to make is hiding around the corner, only waiting for an invitation to come forth.

C. H. CLAUDY

## CARBON PRINTING IN SMALL QUANTITIES.

[The following notes on the citric acid sensitiser for carbon tissue are addressed to the less practised worker of the process, but a word should be said at the same time in praise of a spirit sensitiser such as that made by the Autotype Company. The opportunities for failure in the process are immensely reduced by the employment of this latter—and expeditious—method.—Ems. "B.J."]

Two or three years ago Mr. H. W. Bennett suggested a modification of the bichromate sensitising bath for carbon tissue for home printing. A recent trial proves it to be excellent in practice, and a method which many photographers would find useful if adopted in their workrooms, even if they do not usually work the process. Bennett pointed out that the carbon tissue sensitised at home does not give such good results as that bought ready sensitised from the maker, and that the chief defect was in the lighter tones of the print, where the whites and the very delicate tones merged into one another, and the details, for instance, of a white dress were in a flat even tint; and he discovered that the addition of a few drops of citric acid to the bichromate solution, neutralised by afterwards adding liquid ammonia until the deep orange colour was changed to a yellow, produced the result he desired. The average professional photographer, no doubt, often wishes to print a few carbon prints for his window or a special order, and he finds he must either send the work away or buy a good many more pieces of sensitised tissue than he will need. Then his printers are probably acquainted with the process, and if he tries to do it in his own workroom a good deal of waste and inferior prints are the usual result.

### The Drying Cupboard.

If he will try Mr. Bennett's method he will be able to keep a stock of tissue of various colours and sensitise a few pieces as he needs them, and his assistants will become familiar with the working of the process and able to turn out an order at any time without waste and of good quality. He will, perhaps, hesitate to see he thinks that some elaborate drying cupboard is necessary, but a very simple contrivance will do the work quite well. It may be made easily from a large packing-case, a convenient size for occasional work would be about 4ft. or 3ft. 6in. high and 2ft. wide and about the same depth; it will be more convenient if rather tall and not too wide, as a long strip can be suspended from the top and bottom. It must have a well-fitting door, and plenty of holes at the top and bottom for ventilation; these must be arranged so that they admit very much light. If such a cupboard stands in a corner of the workroom it may have a row of holes, bored with a countersink-bit, along the bottom and top of the back, and of the sides which stands near the wall, but the cupboard must be placed a few inches from the wall to allow space for the air to enter at the bottom and escape at the top of the cupboard.

### The Citrate Sensitiser.

In a damp weather a small lighted spirit lamp should be placed inside the cupboard to dry the tissue, but it will be needed only a part of the time, so a small one holding about 3oz. of kerosene is a suitable size. In winter, if there is a fire in the room, no lamp will be necessary. The tissue should dry in not less than 24 hours and not more than six hours. If it is dried too quickly it will be sensitive, take a long time to print, and give chalky, hard prints; if it is dried too slowly it will give flat, foggy prints, and be quite useless by becoming insoluble. If the sensitising is done overnight and the room is warm, the tissue should be in condition next morning, and should at once be taken out of the cupboard and kept just as carefully from moisture as platinum in an airtight tin, with calcium chloride as a damp trap. It keeps in good condition for a week at least. The sensitising is best made up with potassium bichromate, obtained from the maker of the tissue, and should be dissolved in the proportion of 100 parts to 500 parts of water. When quite dissolved 100 parts of citric acid is dissolved in a few ounces of water, and finally sufficient liquid ammonia to change the orange colour of the solution to yellow. It is a good plan to make up a fair quantity of each, as it keeps well, and is then always ready for use, and can be used over and over again without deteriorating, whereas if only a small quantity is made up it will soon be used up. A few pieces of tissue can be sensitised in ten or fifteen minutes and hung up to the cupboard. The time of immersion varies with the kind

of negative used and the temperature of the air. In summer about two minutes for average negatives, and in winter or for strong negatives three minutes' immersion should be given. It is not easy to cut the tissue up into the sizes required from the band or roll, so it is best to cut off a piece about 7in. long from the roll with a fine saw, such as a dove-tail or tenon saw. This will then cut up into convenient lengths for whole plates and half-plates, allowing a small margin for defects at the edges. A piece about 30in. long will cut up for the two sizes, with but little waste, and is a convenient length to sensitise and dry. A deep whole-plate dish will be large enough for immersing the tissue. It should be filled with the sensitising solution to at least an inch in depth. The roll of tissue is then immersed in it and unrolled slowly with one hand and re-rolled with the other, so that the whole of the back and front are completely covered with solution. It is re-rolled backwards and forwards from one hand to the other (carefully removing air-bells) for the necessary time, and then laid on a sheet of clean glass or zinc face downwards, and a flat, not a roller, squeegee drawn briskly over it to remove surplus solution. It is then lifted from the glass and pinned up in the drying cupboard, with strong pins at the two top corners. It would be as well if the cupboard were lined with blotting-paper. The squeegeeing of the tissue is most important, as it ensures even sensitising. In hot weather the tissue will become very soft and slimy, and should be handled with care, and the solution kept as cold as possible. A small lump of ice may be put into the dish; or if, as will frequently be the case, ice is unobtainable, the bottle containing the solution should be wrapped up in a towel and placed under a dribble of water from a tap overnight, and, if possible, in a good current of air. The evaporation of water from the towel produces a considerable reduction of temperature, and the sensitising may be done first thing in the morning and the tissue will then be ready for use at mid-day.

All this will, perhaps, appear to be a great deal of trouble and possibly expense. The expense at least is very small, and the trouble not nearly as much as the long description would seem to indicate. A sharp boy, who will take reasonable care, could be taught in a few lessons to do all the work of sensitising and drying.

### Printing Preparations.

The speed of the tissue is a little slower than the same brand sensitised by the maker, but an easy method of arriving at the proper time of printing is to put the negatives out, with the actinometer by the side of them, but instead of making a trial of a piece of tissue a strip of ordinary P.O.P. is placed in each frame and exposed until the depth of the print is a little too dark for an untimed proof, but not dark enough for toning. If the negative requires printing up in some parts or shading in others, it should be done when making the trial silver print, and the negative can be marked with the numbers of the tints required for the various parts. This may be done some days before, so that when a day is chosen for printing the carbons the necessary exposures are known and all the negatives are ready for printing. It is a good plan to cut up a good number of strips of paper for the actinometer from one sheet and keep them in a small tin box, as different sheets of paper print out to different colours, which confuses an inexperienced printer in matching the tint of the actinometer. All negatives except those to be vignetted should have an opaque edging for the safe edge, and much trouble can be saved by setting apart a few printing frames for carbon work and using a front glass with the safe edge upon it, made with strips of lantern binding or with black varnish. If black varnish is used a very handy little tool for applying it can be made by "lashing" a wooden match or similar slip of wood to an old spotting brush with a piece of twine, so that the slip of wood projects half an inch or so beyond the fibres of the brush, which is charged with black varnish and drawn along the edges of the negative, the piece of wood acting as a gauge or guide as it runs along the glass edge. A neat black edging can be given very quickly in this way.

If a few portraits for the show-case are to be printed it is of no

great importance if they are reversed, so that they may be printed by single transfer and thus save some trouble and risk of failure. If thick, rough single transfer paper is used it is best to soak it for by single transfer and thus save trouble and risk of failure. Then the exposed tissue is laid down upon it and with considerable pressure squeezed to force the face of the print into perfect contact with the uneven surface of the paper; and it should be allowed to remain between sheets of blotting-paper under pressure for twice as long as would be needed for smooth transfer paper. This will greatly reduce the liability to blister.

#### Patchy Prints.

The carbon printer of little experience will be sometimes troubled with insoluble patches in his prints which refuse to develop and cause dark marks, thus spoiling the prints. These may generally be traced to two causes. The small marks, usually round spots, are caused by the careless use of alum. A grain of undissolved alum has become attached to the printed tissue in the process of laying it down upon the transfer paper or temporary support, and has rendered the gelatine insoluble in the hot water of the developing bath. Larger patches of irregular shape are caused by squeezing the tissue after sensitising on glass or zinc which has not been washed after the last time it was used. Sensitising solution has been left on the surface, it has dried, and when the pieces of new tissue are laid upon it small particles of bichromate have adhered to the wet surface of the gelatine and produced insolubility.

Most of the information given above is well known to the experienced carbon printer, but this article is intended for the photographer who has little knowledge of the process, to encourage him to take up this most beautiful and permanent printing medium.

COUNTRY PRO.

## Photo-Mechanical Notes.

### Mechanical Etching of Engraved Plates.

A METHOD of mechanical etching, in the course of which the strength of the etching bath can be raised or lowered, has been worked out by Emmanuel Spitzer, of 19, Gabelsberger Strasse, Munich, to whom an English patent, No. 21,026, 1907, has been granted.

The invention consists in adding to an etching bath of a certain degree of concentration, an etching fluid of a higher or lower degree of concentration respectively, and at the same time creating a mechanical movement of the etching fluid, both operations taking place in such a manner as to be subject to the control of the operator so as to enable him to regulate them according to the effects which he desires to produce. These effects are an exact reproduction of the blending of all the shades contained in the original combined with a great depth of etching.

If, instead of an etching fluid of a lower degree of concentration, water is introduced into the etching bath containing, for instance, perchloride of iron, the effect is still better, the admixture of water to perchloride of iron, as is well known, causing the temperature of the etching fluid to rise. This progressive rise of the temperature tends to assist the activity and exactness of the etching process.

The following are descriptions of two out of the many ways in which this invention may be carried out:

The plate to be etched is introduced into a basin filled with an etching fluid, for instance, perchloride of iron of 42 deg. Beaumé. During the etching process a quantity of perchloride of iron, of, say, 38 deg. Beaumé is introduced more or less rapidly into the etching bath, this introduction being either continuous or intermittent. The mixture of the new acid with that contained in the etching bath causes the degree of concentration of the etching agent to be gradually lowered.

If the etching bath is provided with an arrangement so that it has an outflow of acid corresponding to the influx of new acid immediately or after a certain time in which the basin becomes full, and thereby creates a current over the plate to be etched, the strength of which is easily regulated, a stronger and deeper etching action will be the result.

An apparatus corresponding to this arrangement, also given as an example, is illustrated in the figures 1 and 2.

The dish *a*, which has at *b* a lower rim, contains the heating or

cooling coil *c, c, c*; further it contains the pipe *d* which is provided with fine holes and which produces an influx of acid, the latter being evenly divided on the right side of the basin, and also the blow (shown cross-hatched in fig. 1) on which the plate *f* to be etched is placed. *J* is the receptacle for the etching fluid and has an indicator for ascertaining the quantity of fluid contained therein. The velocity of the influx is regulated by a tap *h*. The outflow is evenly distributed over the left side, the consequence being an even flow or current of the acid over the plate *f*.

In order to obtain the gradation of shading in even a more precise manner than is possible by artificial heating combined with addition of perchloride of iron of different degrees of concentration,

Fig. 1.

Fig. 2.

to the etching bath, and at the same time to produce a still greater depth of the etching action, the following proceeding may in practice, be recommended:—

The plate to be etched is placed into a certain measured quantity of perchloride of iron of a certain degree of concentration and to a quantity of water, which is also carefully measured, is added, so produce, for instance, a gradual lowering of the degree of concentration of the contents of the etching bath from 42 deg. Beaumé to 32 deg. By the addition of water, instead of perchloride of iron, and its thorough mixing with the perchloride of iron, a rise of temperature is obtained in the etching bath by chemical reaction, sufficient to make artificial heating superfluous.

In order to obtain a rapid and even mixture of the water with perchloride of iron and thus to avoid any unevenness of the etching, the etching bath has to be moved or stirred mechanically. The movement may be continuous or intermittent; in the former case the etching will be deeper than in the latter in consequence of the greater reaction. The addition of water may also be regulated so as to be continuous or intermittent.

### Photo-Mechanical Colour Printing.

In making negative transfers from colour printing jobs the following improvements have been made and patented by Rudolph Schö 13, Jerusalem Strasse, Berlin. (English patent, No. 13,020, 1907.)

For multiple colour printing it is essential that the various forms shall have surfaces of equal size, as otherwise inaccuracies in which the colours overlap would ensue. With the pigment paper it frequently happens that this condition is not fulfilled as the paper becomes distorted in the water or chromate bath that the printing surfaces of the various plates often differ in several millimetres.

According to the present invention the paper is stretched on both sides before and after being sensitised in such a way that it remains practically unchanged during the remaining treatment and is liable of any further noticeable expansion or contraction.

This expansion or stretching of the paper may be accomplished by softening it for several days in clear water free from air bubbles after it is completely saturated squeezing it on to a smooth surface such as a sheet of plate glass as is done in obtaining enamelled surfaces for photographic gelatine papers, whereby the edges may be secured.

the plate by any kind of adhesive. After drying this process may be repeated. The pigment paper when completely dry can be easily moved from the sheet or plate glass, especially if it has been previously coated with talc, wax, collodion, etc.

The sheets of pigment paper so treated are then sensitized in a romate bath and once more squeegeed on to a sheet of plate glass & dried thereon. The paper is then practically protected against y change in size during further treatment.

The stretching of the paper may be accomplished in another way, ., by rolling upon a glazing machine or by hanging it up and ighting it on one side, but the squeegeeing method seems the most venient at the present time.

PHOTO-MECHANICAL PATENTS.

The following patents have been applied for :—

COPYING.—No. 6,275. Improvements in processes for making photographic copies of printed documents, manuscripts, drawings, & the like. Carl von Arnhard, 6, Lord Street, Liverpool.

PROCESS PLATES.—No. 6,276. Improvements connected with the production of process plates. Alfred Charles Hounslow, 18, Southampton Buildings London.

Patent News.

Process patents—applications and specifications—are treated in *Photo Mechanical Notes.*

The following applications for patents have been received between me 15 to June 20 :—

FLEX CAMERAS.—No. 12,925. Improvements in reflex photographic cameras. The Thornton-Pickard Manufacturing Company, Ltd., Arthur Gray Pickard, and Frank Slinger, 6, Bank Street, Manchester.

INEMATOGRAPHS.—No. 13,027. Improvements in obturators for cinematographic apparatus. Arcade Mallet, Birkbeck Bank Chambers, Holborn, London.

RR SLIDES.—No. 13,076. Improvements in photographic dark lides. Harry Bernard Price, 25, St. Aldate Street, Gloucester.

INOGRAPHS.—No. 13,128. Method of, and means for, taking photographs of landscapes. Julius Neubronner, 53, Chancery Lane, London.

UMINATED BODIES.—No. 13,169. Improved means for the convenient observation and photography of highly illuminated bodies. Oswald Hardey Evans, 102, Sandmere Road, Clapham, London.

COMPLETE SPECIFICATIONS ACCEPTED.

ese specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

LOUR PHOTOGRAPHY.—No. 4,745. 1908. The invention relates to an adjustable compensating filter for screen-plate colour photography, already described in Eng. Pat. No. 4,932, 1907 ("B.J.," March 27, 1908, p. 243). Since there are unavoidable differences in the sensitiveness of the emulsion and also in the nature of the light, these differences are taken into consideration, according to the present invention, by arranging in the plane of the lens shutter opaque sectors, such as are indicated by S R<sup>1</sup>, S R<sup>2</sup>, S R<sup>3</sup>—S V B and S V<sup>1</sup>—S V<sup>2</sup> in the drawing, with the object of covering the transparent sectors R—Vt and B V of the screen E (Fig. 14 of the main application) in such a manner that the simultaneous photographing of the three colours will give a correct result. These opaque sectors may, for example, be spread out or be folded in the manner of a fan by means of a suitable device. They may also be composed of lamellæ, independent of one another, capable of sliding in slots in the lens mount.

Instead of a three-coloured screen, that is to say, of a screen built up of strips, mosaics, sectors, tinted with the pure colours, there may also be employed a screen of a single colour in outward appearance, having the property of transmitting only the three parts of the spectrum that correspond to the pure colours referred to in the description of Fig. 6 of the main application.

Screens of this kind may be made by cementing two gelatinised

glass plates or discs together by means of Canada balsam, of which one has a colour that will absorb the rays lying between the red band and the green band of the spectrum, whilst the other has a colour that absorbs the rays lying between the green band and the blue-violet band.

These screens are, however, more difficult to make than the three-colour screens of the main application, and generally they render necessary the co-use of compensating screens for the purpose of enabling all three colours to be photographed at one and the same time. Charles Louis Adrien Brasseur, 121, Potsdamerstrasse, Berlin; and 10, East Fifteenth Street, New York.

CINEMATOGRAPH PORTRAITS.—No. 13,407. 1907. The invention, which has already been described in the "B.J." for April 24, 1908, p. 330, consists in the cinematographic apparatus for exhibiting intermittently moving animated pictures, in which the pictures are arranged in rows side by side upon a sheet of paper in such a manner that, on coiling the picture sheet to the shape of a hollow cylinder and on laterally displacing the marginal edges closing the cylinder, to the extent of the width of one of the picture rows, a succession of all picture rows in a helical line is attained. The picture sheets are preferably produced in the form of postal cards, so as to be suitable for exhibition in a standard size of cinematographic apparatus. Hans Voss and Hermann Simon, 186, Wandsbeker Chaussee, Hamburg.

DRYING BOXES.—No. 14,505. 1907. The claim is for a drying box or cupboard, having the following features :—

- (1) Vertically sliding, balanced door, and elongated handle.
  - (2) Gas jets at the base, with inspection and lighting flaps.
  - (3) Inter-changeable racks, on which short or long prints may be suspended without creasing.
- B. J. Hall and Co., Ltd., 39, Victoria Street, London, S.W.; and Benjamin James Hall.

The following complete specification, etc., is open to public inspection before acceptance under the Patents Act, 1901 :—

DARK-ROOM LAMP.—No. 12,649. Photographic dark-room lamp for variously coloured light. Mützel.

Analecta.

Extracts from our English weekly and monthly contemporaries.

Daylight Printing of Gaslight Papers.

With regard to the actual exposures for different grades of negatives (writes Mr. G. E. C. Morris in "The Photographic Monthly" for July) I give the following, from my own experiments, as approximately correct for Wellington S.C.P. I have not tried other makers as yet :—

	Distance from window.	Maximum exposure.
Dense negatives .....	4 ft. ....	6 secs.
Medium negatives (average) ..	4 ft. ....	4 secs.
Soft negatives .....	4 ft. ....	2 secs.

This is assuming the ordinary daylight is used from 10 o'clock in

the morning till 3 o'clock in the afternoon, without direct sunlight, or, in fact, without the sun shining at all. Daylight, of course, is a variable quantity, and no doubt at the outset over-exposure will have to be contended with. It is as well also to bear in mind that the distance one can work from the opening varies according to the size of the sliding window frame. My own window has an aperture measuring 2ft. 6in. by 1ft. 6in. This admits a good quantity of light, but, for all that, I often find it necessary to print at closer quarters on very dull days or towards evening, sometimes as near as a foot from the window. But it is not advisable to print at closer quarters than 4ft. until a little experience has been gained. The opening of the slide should always be at least twice as large as the printing frame, or there is the danger of unequal illumination. The measurements given above (viz., 2ft. 6in. by 1ft. 6in.) will be found to be a very good all-round size.

### The Camera in the Mountains.

THE difficulty (complained of by so many beginners) that mountains will look so small when reproduced (writes Mr. Will A. Cadby in "The Amateur Photographer and Photographic News" for June 30) can be got over by the use of a lens of longer focus than that they have been using, but this, of course, necessitates a camera with a long bellows extension. The Adon telephoto, used alone, is a most satisfactory instrument for this purpose, as with it we can have our view just what size we please, added to which advantage it is a light and small lens to carry. The convenience in the mountains of being able to alter the size of the picture is hardly realised by those who are used only to photographing on the level, for if we leave our coign of vantage, from which our picture appears at its best, we may have to descend out of sight of our object altogether, and when we have climbed a nearer slope to get our view on a larger scale, we may, probably shall, find our picture entirely altered. But another way of getting a rise out of the mountains, so to speak, is, if possible, to raise oneself and the camera on to higher ground. Often a hundred feet or even less will make all the difference to our picture, for this arrangement lowers the foreground and raises the distance, which is exactly what we want, and, what is more, gives us glimpses of the intervening country. Now these glimpses are most valuable, for they help materially to suggest what a long way off the mountains on the horizon are. Seen from a lower standpoint they appear as diminutive peaks immediately behind the nearer ranges, their lighter tone seldom being pronounced enough to alone suggest the great expanse of valley that in reality separates them from the foreground. But the tone value of each succeeding ridge of hills must be carefully observed and preserved in our negative, for, after all, it is the rendering of that faithfully that suggests the distance.

### Photography at the Franco-British Exhibition.

With reference to your notice *re* photographing at the Franco-British Exhibition (writes Mr. A. E. Dunn in "Photography and Focus" for June 30), I found that permission could be fairly easily obtained by writing a few days before you intend visiting, and then, on your arrival at the exhibition, to leave your camera in the cloak-room, as you have no permit, and then make straight for the administration office, which is situated near the Wood Lane entrance. Arriving there, you will be directed, after stating your requirements, to the press office in the same building, where, on stating that you have already written asking for a permit, and on writing a declaration that you will not photograph in any of the buildings or publish any of the photographs, a permit will be granted. You will find that it is rather a nuisance to attempt to do much work there, as every official is authorised to ask you to produce your permit whenever he sees you using a camera, owing to the entire rights for photographing, except under the above conditions, being reserved to one firm only.

FREDERICK BOEHM, LIMITED, is to be the name of the limited company (capital £60,000) formed from the business which Mr. Frederick Boehm has carried on for exactly twenty years. Mr Boehm's managers, Mr. Kunzen and Mr. F. Schaer, who have long been connected with the business, will join the board as directors, but the conduct of the business will not be affected in any way, and the firm will continue as hitherto to act as agent for Merck and other makers of fine chemicals, photographic and otherwise.

## New Books.

"The Photographic Annual, 1908" (Incorporating the Figures, Facts, and Formulae of Photography). Edited by H. Snowden Ward. London: Dawbarn and Ward. 1s.

As a most useful compilation of the working solutions of which the photographer has to make use, "Figures, Facts," has established itself. In giving it a form which presumably implies annual appearance, the publishers have greatly extended the subjects submitted to its "skeletonising" method, while the sections contained in the previous editions are more fully treated. For instance, the formulae and prescriptions for the use of process workers—photo-engravers, collotype platemakers, lithographers, and three-colour workers—are the subject of important sections. Ozotype, ozobrome, bil, and bromoil are also subjected to the condensed treatment which conveys the essential facts of a process in few words. The whole revision has evidently been done with much care and so recently as to include the later formulae for the Autochrome process, for example. Mr. Snowden Ward has relied on the very clear arrangement of the volume, and has replaced the index to the many items by a glossary in which are "facts, figures," not easily classifiable in other sections. The "glossary" shows a tendency to become unduly miscellaneous in character, as when it turns from first aid to the injured (including what to do when you are alone except to a cinder in one eye) to furniture cream and salts of wormwood. In this section, it is true, a large number of useful chemical facts are contained, and some useful translations of German technical terms, but our own belief still is that much of the matter can be classified, and that an index would still provide a needed key to the many practical hints on every page of the volume. However, we must refrain from saying more on this point, seeing that Editor Ward is adamant as to a reversion to the previous arrangement. Typographic and other errors appear to have been eliminated to a high degree of completeness from the "Annual," which altogether is an excellent expansion of a most useful compilation.

## New Apparatus, &c.

The Busch "Sellar" Combined View Finder and Level. Sold by Emil Busch Optical Co., Charles Street, Hatton Garden, London, E.C. Sole wholesale agents: Houghtons Limited, 88-89, High Holborn, London, W.C.

Some time ago we published the translation of the article by He K. Martin, in which the principle of this new instrument is described. We need not therefore repeat, except to say that the finder consists simply of a two-curved metal mirror, and is thus quite distinct from all the other forms of finders on the market. In the commercial form now available this mirror is hinged to a metal base, which in turn

Model A.

is hinged to a similar base, the one pair of hinges being at right angles to the other. This device allows of the finder being quickly changed over when using a magazine or other box camera first for, say, "landscape" pictures, the next for "uprights." This is the case in the two models of the finder which are made—one is practically any camera, and the other for folding hand-cameras—

it to which things can be easily so arranged that the base of the camera will automatically close (and enclose) the finder. In the case of both patterns the view is seen by looking straight on the finder, and it is seen the right way up and unreversed. The camera is level at the same time that the view is being

Model A (Closed).

Model B.

and this, without the operator having to make an effort (quite futile) to do two things at once. In the case of the Sellar, "finding" and "focusing" are one and the same operation, and this one should recommend this new finder. Its small size, clear view, and moderate price are other points in its favour.

"Sellar" is made in three sizes (Nos. 1, 2, and 3) intended for the following:—

For lenses of focus	3½ in. to 4 in.	On plate 3¼ in. by 2¼ in. or 3½ in. „ 2½ in.
5 in. to 6 in.	„	4½ in. „ 3½ in.
6½ in. to 7 in.	„	5 in. „ 4 in.
7½ in. to 8½ in.	„	6½ in. „ 4½ in.
7 inches	„	3½ in. „ 2½ in.
9 inches	„	4½ in. „ 3½ in.
10 inches	„	5 in. „ 4 in.
14 inches	„	6½ in. „ 4½ in.

No. 3 is made specially for the Busch "Bis-Telar" and for the combinations of lenses used alone. The price of the finder of No. 1 is 6s.

## New Materials, &c.

"Type" Oil Printing Papers. Made by the Autotype Co., 74, Abchurch Lane, London, W.C.

The Autotype Company have introduced special gelatinized paper printing in two varieties—white (No. 1) and toned (No. 2)—might be expected, both papers seem admirably suited to the work. The papers are slightly rough—that is, of about the texture of "rough" in the case of bromide papers—and the tint of No. 2 paper is a faint brownish cream, admirably suited to the work. Hitherto the great difficulty that oil printers had to surmount has been the finding of a paper coated with a film that would stand a considerable amount of hard usage. Various papers, transfer papers, and various special papers have been tried, but in most cases it has been found that after a small amount of brush work the gelatine begins to show small cracks.

This effect is soon followed by the stripping of the gelatine and the consequent destruction of the picture that was on the paper. The gelatine that will stand plenty of work is most essential, and we have tested these new Autotype papers very carefully with regard to this particular quality. So far we have not found anything disturbing the gelatine in the slightest degree, though tried vigorous "dabbing," violent "hopping," and most of the "brushing" for considerable periods. In fact, the paper is an ideal one for the purpose, and we can recommend it without any hesitation. It is sold in packets containing one dozen sizes varying from 5½ x 4½ to 15½ x 12½ at prices ranging from 5s. per packet. The most useful sizes, 9 x 7 and 12½ x 9, are 6d. and 3s. 6d. per packet, respectively. Oil printers have no cause to grumble at the materials at their disposal. There is no need to trouble with home-made papers and pigments, and the want of good brushes is no longer a valid excuse for a trip to the brush-maker. All the materials required, and of the very best quality,

are now available in London, since the final want, that of a good paper, has now been supplied by the Autotype Company. The question of whether "oil" is a photographic process is being discussed pretty freely at present, but whether photographic or not, it is evident that it is a process that has come to stay, and its importance is amply proved by the efforts of various manufacturers to supply the material required.

The "Easy" Retouching Medium. Made by Geo. R. Henderson, 162, Ellison Street, Hebburn-on-Tyne.

This sample of negative retouching medium, put on the market by Mr. Henderson, is evidently one of the many mediums of which turpentine is the vehicle and, should thinning at any time become necessary, turpentine must be used for the purpose. Gradual evaporation of the solvents sometimes necessitates thinning, and, of course, some retouchers prefer to employ a thinner medium, being able to get their effect with less application of lead, and consequently without the need for excessive tooth. The medium may be applied to a small portion of the negative by touching the tip of the finger on the cork of the bottle after inverting the same, and rubbing on the negative with a circular movement until it commences to feel tacky. Or where the whole of the negative is to be covered—the medium then acting to some extent as a protective varnish—a piece of soft cloth may be placed over the finger and held to the bottle neck while the bottle is tipped up, sufficient medium being thus obtained on the cloth to cover a half-plate negative. The tooth formed as soon as the medium is tacky is a pleasant one to work on, either with a pencil as hard as HH or as soft as BB. It is quite easy to pile on more lead than is ever wanted, except under quite extraordinary circumstances. One point especially appealed to us when working with the medium, and that is the absence of any tendency to brittleness. Some mediums dry very hard, and when a hard pencil is used the coating is so friable that scratchiness of effect is obtained. We have had a good deal of satisfaction in testing the medium, and that pleasure which arises from working with materials which are perfectly adapted to the requirements.

"Rajar" Collodio-Chloride P.O.P. Made by Rajar, Ltd., Moberley, Cheshire.

A sample of the collodion paper which Messrs. Rajar, Ltd., have now added to their list of manufactures has been used by us with very satisfactory results in both the matt and glossy varieties. The paper tones readily in both the sulphocyanide bath—which is that specially recommended for the glossy variety—and in the acetate bath, which is used as a preliminary bath to platinum for black tones on the matt paper. The latter method is the most advantageous mode of treatment of collodion paper, and the "Rajar" product responds to it in an excellent manner. The paper does not give trouble by curling in the baths, and its film is free from any abnormal tendency to crack and split after the prints are finished. Treated as C.C. paper requires, the new product is evidently capable of exceedingly good work.

### CATALOGUES AND TRADE NOTICES.

SECOND-HAND APPARATUS.—In their July list of second-hand photographic apparatus the City Sale and Exchange, of 54, Lime Street, E.C., advertise a number of bargains in cameras and lenses, including practically all the varieties at present on the market. The firm also draws attention to the fact that they specialise with the exchange of apparatus in either part or whole payment for any other goods that may be selected.

A "SIBYL" BOOKLET, newly issued by Newman and Guardia, 90 and 92, Shaftesbury Avenue, W., describes in detail this highly serviceable pocket camera, the practical efficiency of which deserves all the emphasis given it in the booklet.

RECENT WILLS.—James Wilkinson, Alma Road, Birkdale, Southport, and Manchester, retired shuttle maker and photographic appliance manufacturer, £11,006.

William Anderson, sometime photographer, 364, Hamilton Place, Partick, and latterly residing at 12, Broomhill Avenue, Partick, £6,966 10s.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, JULY 4.

Rugby Photographic Society. Excursion to Birdingbury. A. W. Fell.  
 Balham Camera Club. Outing to Hampton Court.  
 South Suburban Photographic Society. Excursion to Rochester. F. N. Palmer.

#### SUNDAY, JULY 5.

United Stereoscopic Society. Outing to Dorking and District.

#### MONDAY, JULY 6.

South London Photographic Society. Annual Jumble Sale.

#### WEDNESDAY, JULY 8.

Manchester Amateur Photographic Society. Excursion to Church Stretton.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the annual general meeting, held on Thursday in last week, the report, presented by the hon. secretary and treasurer, Mr. E. R. Human, made reference to the lamented decease of Mr. A. L. Henderson, and to the award of the Henderson Medal to Dr. C. E. K. Mees.

Upon the motion of the chairman, Mr. T. E. Freshwater, seconded by Mr. R. Beckett, the report and balance-sheet were adopted.

The following were elected as officers for the coming year:—Trustees, T. E. Freshwater and A. Haddon; committee—Messrs. J. S. Teape, H. C. Rapson, R. Beckett, A. E. Smith, J. Burgess, W. R. Stretton, Charles Greenwood, O. S. Dawson; hon. lanternist, E. T. Wright; hon. librarian, W. J. Ferry; hon. secretary, treasurer, and recorder, Ernest Human; affiliation delegates, H. C. Rapson and Ernest Human.

A vote of thanks to the hon. secretary and treasurer was proposed by Mr. Beckett, who said that during the twenty years he had been a member he had never known a secretary who had done his work better. This was seconded by Mr. Teape, who fully endorsed all that the proposer had said. Mr. Human's reply concluded the meeting.

## Commercial & Legal Intelligence.

LEGAL NOTICES.—A first and final dividend of 2s. 9½d. in the £ is to be paid in the bankrupt estate of Percy John Swain, photographer, of 2a, Davey Place, Norwich, formerly carrying on business in partnership with Louis Smith as Louis Smith and Co.

Charles George Sinclair, photographer, of 264, Victoria Street, Great Grimsby, has been granted an immediate discharge in bankruptcy, subject to payment of a dividend of 10s. in the £1.

A receiving order in bankruptcy has been made against Walter George Lewis, photographer, 1, Seymour Street, Bath, on a creditor's petition.

HIS HAT IN THE PHOTOGRAPH.—The case of Dickinson v. Earle was resumed by Judge Woodfall at Westminster last week. It was a claim for five guineas for a print. The case for the plaintiff was that defendant, Captain Earle, gave an order that he should be included in a picture of last year's Eton v. Harrow cricket match at Lord's, and he was to be next to Lord Euston in the picture. The order covered a print of the picture, for which five guineas was to be paid. Captain Earle duly appeared in the picture, and then said his financial position had altered, and he did not want the print. Next some point was raised that he appeared bare-headed, and should have had a top hat on.

Captain Earle gave evidence that he sat for his photograph, and chose from the proofs the one in which he appeared in a top hat. In the picture he appeared without a hat. Directly he saw the picture he pointed out the mistake, and said it must be altered, or he would not have it, "because I haven't much hair."

His Honour found for the plaintiff, with costs, holding that the defendant had not proved the alleged stipulation that he should wear a hat in the engraving.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### WRITTEN TESTIMONIALS.

#### To the Editors.

Gentlemen,—In reply to your correspondent, "Marcus" evidently has not given both sides of the question. I will furnish you with the missing part of the story. "Marcus" says that about eight months ago he dismissed an assistant; but the latter was never missed at all, but left on mutual terms because he desired not to accept less wages in the winter months. "Marcus" also says an assistant asked to come back. This, however, is not the case. "Marcus," in conversation with the assistant, offered him the vacancy told him that he would rather have him than anyone else, as he was leaving his business for a holiday. To oblige "Marcus" the assistant gave up a permanent position on the understanding that his employment should hold good until Christmas. On his return his employer gave the assistant notice to leave through a technical part of business only. True, this assistant did set up business opposite it was months, not weeks, before he exhibited "Marcus's" reference. Why did he do this? Because "Marcus's" business front placarded with the following, in large type:—"No connection [here using the assistant's initials] opposite." "Beware of the door photographers." "We lead, others follow." "We competition." "Postcards at 2s. 6d. per dozen." Not satisfied with this, "Marcus" advertised continuously in a local paper cautioning the public not to purchase postcards or photographs of any description from any but well-known reputable photographers, as they fade and become useless soon afterwards. He also suggested that others were using "Genuine" rubbish, while his were only "best English materials." Not a lot of this kind of advertisements had been used did the assistant put the testimonial complained of in his show-case. And when "Marcus" do when he first heard of it? He challenged the assistant by a placard in his window (using his name) to inform the public that he was dismissed at a minute's notice (which, by the way, was untrue without any fear of contradiction). Why doesn't "Marcus" sue the assistant under false pretences for using the testimonial especially after being advised to do so by his solicitor? He also told the assistant using a phrase such as "work equal to any as by your own townsmen." This is also absolutely incorrect. The expression used was: "Beware of spurious advertisements in circulation. Read this testimonial and form your own conclusions whether I am a practical man or not." Now I will ask my personal readers to look at both sides of the story and judge for themselves as to whether the assistant's action was justifiable or not in a town where originally there was but one photographic studio.

[Our correspondent's relation to the writer of the letter appeared in last week's "Journal" is quite obvious from the recital. It is contrary to our rules to allow the correspondence columns of the "Journal" to be used to air private grievances for that reason we suppressed the identity of the writer of last letter, whom we called "Marcus." Our present correspondent us permission to publish name and address, but it is better the scene of the lively amenities of photographic competition remain unnamed.—Eds., B.J.]

### SCULPTURE OR PHOTOGRAPHY.

#### To the Editors.

Gentlemen,—I notice in the current number of your journal in which the writer, Mr. F. C. Tilney, talking sagely about art and moral rights, absolutely identifies my picture now in exhibition of oil prints at the offices of the "A.P. and P.N." statue by the late Onslow Ford, which I admit and regret I had heard of till now. True, some time ago I happened to see a reproduction of a statue, torn from some magazine I think, which I never knew nothing about except that it particularly pleased me much so that I set about endeavouring to produce a similar p

graphy. My results did not satisfy me and it was put on one. Later I took it up again, and, with the reproduction before me, I painted on my print in body colour, altering and correcting it as I was able, more as an exercise than anything else. Subsequently a copy was made in the camera, and thence the oil print.

The above reasons it is not a picture that I should exhibit in any ordinary way, but do so now in an "oil" exhibition, as it, in my opinion, shows to a peculiar degree the especial characteristics of the process, according to my idea of what it is and should be.

Tilney, in stating that solely by the "control" of the pig-brush, one can photograph a statue and give it the appearance of life, pays a high, but, I think, undeserved tribute to the possibilities of the process.

Nowhere in the same number is a critique, if such it may be, and amongst various disparaging remarks on the exhibition, the writer says:—"Imitation is the sincerest form of flattery." I ask of what is this exhibition in imitation; is not this the first time that a collection of prints of various workers has been got together in London, thanks to the enterprise of the artist and P.N.? Certainly I have never yet seen in a private gallery a show of photographs so tastefully got up and artistically arranged, and withal a collection of such good work as that now at the gallery of Mr. Acree.—Yours truly,  
BERTRAM PARK.  
Fellows Road, Hampstead, N.W.

Whatever bad things we have said of the oil process, and how Mr. Park thinks we are its natural enemies, we have never that it justified the exhibition of a print which was a plagiarism on the work of art. Nor apparently is Mr. Park with us in our hopes that the oil process will advance pictorial work in the direction of graphic qualities. Why should he be? he starts with some non-photographic.—Eds. "B.J."]

## Answers to Correspondents.

*Matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.

*Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C.*

*For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. No unmounted copies of each photograph must be sent with the*

glass behind negative with no improvement, but by varnishing negative cures it, but everyone does not like their negatives varnished. Light is properly centred in every way. Is there any cure?—B. O.

1. Plate glass is often used. Try Hetley and Co., Soho Square, London, W.C. 2. Mercury vapour is largely used now. The tubes are placed behind a ground glass screen, and the direct (not reflected) light used. The light is very highly actinic, and particularly suitable for working from large negatives. 3. The difficulty probably arises through the ground glass being placed behind the negative instead of behind the condenser. When using a really diffused light, such markings rarely occur. We deal with the point on another page.

Q. S.—We know the former only. We should use it only for bromide, platinum, or carbon prints, though it might be employed for P.O.P. if applied only to the edges.

W. C. E.—We cannot say. Better apply to Fallowfield, 146, Charing Cross Road, W.C., who can get the work done on the spot.

P. SKES.—Certainly, the apertures you name will not give a range of speeds of 1/10 to 1/1000. If the widest slit is 5 in, the narrowest should be 1/20 of an inch. A slit of half the width gives half the time of exposure, and so on. An accurate test of the shutter is not an easy matter. We should advise you to send the camera to the actual makers to have the speed verified, or you might get the same done by Kershaw, St. Columba Street, Leeds.

APERTURE.—The "effective aperture" may be a little larger than the value (f/8), which you have correctly calculated from the actual diameter of the diaphragm and the focal length. This is due to the condensing action of the front lens, but we do not think it would amount to the difference found. You had better measure the effective aperture, say, by Mr. Piper's recent method.

M. I.—Certainly, the various toning processes, such as copper, uranium, etc., can be applied with a brush, but the process is not a very satisfactory one, and the results are not above suspicion as regards permanence. There are no text books on this branch of work, though occasional articles on the subject appear in the press. Our own opinion of the process is that it is not worth all the trouble, but you had better make one or two trials with formulae, such as you will find in "Toning Bromides," by C. Winthorpe Somerville. (Dawbarn and Ward, Ltd. 1s.)

NETTA.—Dorrett and Martin, Belle Vue Road, Upper Tooting, London, S.W.

OPALINES.—1. H. Cornthwaite, Dale End, Birmingham. 2. Reigate.

BROMOIL.—I shall be much obliged if you are able to enlighten me as to the cause of bromoil print taking up pigment in a patchy or streaky manner. The markings, some of which have quite defined edges, are most present or most visible in flat masses of tone, such as skies, which it consequently becomes impossible to cover with an even tint, as can be done in an oil-print. Is the cause likely to be connected with uneven bleaching, and what is the preventive of the latter? Some of my bromide prints have bleached irregularly (also in streaks and patches), but I left them in the ozobrome solution until they appeared to be bleached equally all over. I used the solution specially prepared for bromoil.—

AQUARIUS.  
It is very difficult to attempt any answer to your question, as the effect is very unusual. A similar difficulty in bleaching is sometimes met with in the ozobrome process, and also in sulphide toning, but no explanation of the uneven bleaching is known to us. Your pigmentation difficulty is no doubt due to the uneven bleaching. We have only met with the trouble two or three times, though we have treated some hundreds of prints. In every case the trouble vanished on treating a fresh print, and it appears evident that it is due to some special circumstance attending the preparation of the original bromide print.

J. C. W.—See answer to "Aquarius."

PHOTOGRAPHER.—You must send your name and address when asking queries.

CLEANING DAGUERREOTYPES.—A customer has sent me two Daguerreotypes to clean. They are nearly obliterated by metallic silver, with which you are no doubt familiar. Years ago I used to clean these, but have quite forgotten the formula. I believe it was iodine and iodide of potass. After it was dried in spirit and warmed to complete the drying. If you would kindly give me the correct proportions, etc., I shall be glad. The plates are sixty years old, and

are very valuable to my client. I do not wish to try experiments on them.—A. S. LANE.

The solution used is weak potass. cyanide solution. You may refer to the article in the "Almanac" (1907), page 767, taken from the "B.J.," November 3, 1906. Unless you feel sure of your work you had better place the picture in the hands of an expert restorer, such as Mr. E. W. Foxlee, 22, Goldsmith Road, Acton, London, W. CANADA.—1. Certainly. 2. No, not with the same characteristic surface nor with precisely the same tones. 3. Certainly, the best collodion papers will lie in the baths without curl. 4. Your informant's description of paper is vague. Certain additions may affect the permanence of the prints, but if toned with gold, followed by platinum (which is the best procedure for collodion papers), all leading makes of this material, such as Paget, Leto, Ilford, Kodak, Criterion, Rajar and others, will give permanent prints.

CHEAP POSTCARDS.—I recently took four men in a group for twelve postcards (3s.). I posted these to them, and they were not satisfied. They brought the postcards back to the studio. I told them the pictures were plenty good enough for the price paid, and I refused to take them again. They went away, but next morning when I opened the door the twelve postcards had been dropped into the letter-box. What am I to do with them?—VEXATIOS.

All you can do is to sue the men for the amount of the cards, though we doubt if it will pay you to do so. As you do not send a card we cannot say whether they are up to the average expected in such work.

TONING BROMIDES.—1. Will you give me a formula for a very cold sepia tone on bromide paper? 2. Formula for developer for bromide paper to be toned sepia, as I believe the developer used governs the tone of the print?—SEPIA TONER.

1. The less the exposure and the more forced the development the colder the tone usually. Additions of mercuric chloride solution to the ferricyanide bleacher darkens the shade of the toned print, but the permanence is open to question. 2. The particular developer is not very important and has not much effect on the tone. Amidol is as good as any.

OLD LENS.—We have in our possession a lens marked "Derogy's Crown and V.R.," with patent underneath rack and pinion, total length, including hood, 5½ in.; size of lenses back and front combination is 2¼ in.; also two other lenses for inserting in centre, one measuring 1¼ in. and marked "Lens for smaller size," and one measuring 1¼ in. and marked "Lens for larger size." These lenses are easily inserted by giving one turn to the whole lens, which then divides in the centre. The stops are also inserted in this manner. Any information you can give of the above, as to the sizes and value of same, will be esteemed a favour.—C. H. F.

1. This is a very old make of lens introduced by Derogy of Paris some thirty or forty years ago. We have answered more than one query with regard to this form of lens lately. The object of the two additional lenses is, the one to lengthen the focus of the instrument, and the other to shorten it. As you do not mention the focus of the lens—its diameter and length of tube are no guide—therefore we cannot say what it should be expected to cover. However, at the time this was made, lenses with a diameter of 2¼ inches were generally termed half-plate lenses. These lenses have little market value at the present day. The best way of getting at its value is to try and see what it is worth to you in daily work. 2. No such list is published.

LENS NOT WORKING TO FOCUS.—I have recently bought a portrait lens, said to be for whole-plate pictures. It is about three and a quarter inches in diameter, and bears the name of "Voigtlander, Wien und Braunschweig." I find that it gives a beautifully sharp image on the ground glass, but I cannot get a sharp negative with it, it is all out of focus. One or two friends suggest that the fault must be in the camera, but I have tried that with two other lenses and got sharp negatives with each. The lens is not fitted with stops, and I see a sort of scale without figures marked on the sliding tube of the mount. What can that be for? Any information you can give me I shall be thankful for.—T. NOADES.

This is clearly a very old lens. All the earlier lenses issued by Voigtlander had a chemical focus, and it was therefore necessary, after the image had been focussed on the screen, to make a correction for that. The fine scale on the sliding portion of the mount

is to show the extent the lens has to be racked out after focus. The nearer the lens is brought to the subject the greater is the difference between the optical and the chemical focus, and has to be taken into consideration.

UNMOUNTING PRINT.—A customer has brought me some print mount in an album. Most of them are unmounted, but a few on mounts. These I have soaked off, all but one, which is on a thick board. This one I have soaked in cold water for 24 hours and it was as tight on as ever. Then I put it in very hot water for a time, still it would not move. Can you tell me how to do with it, as I told the lady I could get all the pictures off the mounts, and I do not like to say I have failed with one. BOYDE.

Without knowing what was the mountant used for this print it is difficult to say how it is to be got off. However, if the print cannot be got off the mount the best thing will be to get the print off the print. With long soaking the mount will become soft throughout its thickness, and the different layers of paper will then be separated and stripped away until the last one is reached. If that cannot then be stripped off it may be rubbed away from the picture, piecemeal, with the finger, leaving only the picture on the last part of the work will require some little care.

SUSPECTED PLATINOTYPES.—A member of my family has had several portraits taken. They are printed in platinotype, or, at least, platinotypes were charged for, and a receipt given for such. On examining several of them it occurred to me, owing to their dark colour, that they are not really genuine platinotypes, but bromides. Is there any simple test that I can apply so as to tell if they are platinum or bromides? Also, if they should turn out to be the latter, can the photographer be compelled to return the money paid for them?—A DABBLER IN PHOTOGRAPHY.

A very simple test is a saturated solution of bichloride of mercury. If a few drops of this be put on a bromide print the image then will be bleached out; but if a genuine platinotype treated in a similar way there will be no effect. As regards the return of the money paid, certainly he will have to return it. Furthermore, he can be prosecuted in the police court, under the Merchandise Marks Act, for fraudulent misrepresentation. The person who paid for the photographs can prosecute.

#### NEW COMPANIES.

KENT-LACEY STUDIOS.—Capital £6,000 (£1) (1,000 5s. preference shares, cumulative preference). To acquire the business and undertaking of Kent and Lacey, of 104, Terminus Road, and 1, Gildridge Road, Eastbourne; 134, Weston Road, Brighton, and 25, White Horse Road, Hastings, to adopt an agreement with S. Lacey and to carry on the business of photographers, etc. None. 1, Gildridge Road, Eastbourne.

MUENZER, LTD.—Capital £25,000 (£1) (12,500 preference shares, 1s. each). To acquire the business and undertaking of Muenzer at the Heliosgraphic Works, 336-340, Chester Road, Cornbrook, Manchester; (2) business of photographic artist, art dealer, and picture framer, carried on by him at 71-75 Grosvenor Road, Manchester, and to carry on the business of Great Britain Fine Art Company. None. 1, Chester Road, Cornbrook, Manchester.

\* \* NOTICE TO ADVERTISERS.—Blocks and copy are received by the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears on the test portion of the paper.

### SUMMARY.

Photographic Convention.—Next year's meeting will be held at Canterbury with Mr. H. Snowden Ward as president. The name of the president for this year, Sir Cecil Hertslet, appears on page 523.

Two novel suggestions on making portraits of children in studio were recently given before a Convention meeting in London. (P. 527.)

Death of Mr. Henry Lomb, one of the original founders of the photographic firm of Bausch and Lomb, has taken place. (P. 533.)

Old-told tale of the need of ascertaining costs in running a photographic business is repeated in a paper read before the Photographic Association of Illinois. (P. 528.)

W. Michell concludes the article on the copying of faded photographs with some hints on avoiding grain in preparing copies. (P. 526.)

Two minor points in the making of diagram lantern slides are mentioned on page 522.

Photography at the Franco-British.—Numerous applications for permission to photograph appear to have led to a standing order which persons can obtain permission to use a camera at the rate of one shilling per day. (P. 522.)

Patent for self-developing papers has been taken out. (P. 534.)

Last lecture by Dr. S. E. Sheppard on the chemistry of photography appears in an abridged form on page 529.

Photographers in the North have now the opportunity of seeing the collection of pictorial photography at the Newcastle Art Gallery. (P. 534.)

Formulae for blocking out mixtures have been given by Mr. S. E. Sheppard. (P. 531.)

Recent paper on the economy of modern electric lamps of the Edison and Tantalum types (and discussing also recent advances in the use of mercury-vapour lighting) has been published in "Nature." (P. 531.)

### EX CATHEDRA.

**The Convention.** At the time of writing half of the Convention week at Brussels is gone, but the record attendance and the success of the gathering have already justified the foresight of those who last July supported the acceptance of the invitation from the Association Belge. Equally satisfactory, too, is the fact that leading opponents (on constitutional grounds) of a Brussels visit are among the most enthusiastic conventioners this week in Brussels. Under the presidency of Sir Cecil Hertslet, the formal business of the Convention has passed off with all imaginable smoothness, while in the more informal association of members which makes up an important part of the Convention proceedings, nothing more than has been done by Sir Cecil could be expected of any president. At the annual general meeting held on Tuesday evening it was decided to hold next year's Convention at Canterbury under the presidency of Mr. H. Snowden Ward.

**A New Intensification Formula.** M. George Le Roy, in a recent note to the French Photographic Society, has recommended the addition of a little commercial hydrogen peroxide solution to the solution of mercuric chloride used for intensification. The mixture is found to possess greater activity and rapidity of action, and is able to bleach negatives which resisted the action of the plain or acidulated mercury solution, owing, it is thought, to imperfect fixation. The suggestion appears to be that the peroxide acts on the compounds in the film of the negatives which oppose the action of the mercury solution, though we cannot believe that intensifiers compounded on this principle would answer expectations.

**Photographic Copyright in Russia.** It is hardly surprising to learn that photographs at present enjoy no protection against infringement in Russia: in this, as in many other matters, Russia is about in the same state as in the middle ages. According to a German contemporary, attention is being called to the disadvantage at which Russian photographers stand in comparison with those of other European countries, and an appeal is to be addressed to the Duma for a remedy for the existing conditions. Probably the Duma is too busy speculating as to what will be happening to it in, say, a week's time, to pay much heed to creating privileges for photographers, but it is nevertheless interesting to hear that some combined action is being taken, and that among the societies represented is an association of professional photographers.

**"Photo-Finishers."** This not very graceful compound word has been adopted by an American contemporary for the specific description of persons carrying on the business of developing, printing, etc., for the trade.

Apart from the philological defects, which are sufficiently obvious, the term is not the happiest, and would be most generally understood in this country to apply to persons doing the working-up in black and monochrome of photographic enlargements, whereas the intention is evidently to apply it to individuals and businesses whose work is less special, being limited to the treatment on a large scale of plate and film exposures and their perfectly "straight" printing in P.O.P., bromide, or other popular process. Yet, as our contemporary asks: Can a more fitting or intelligible word be found?

\* \* \*

#### **Cameras at the Franco-British Exhibition.**

Experiences in regard to permission to photograph at the Franco-British Exhibition appear to have been very various. Apparently permission to use a hand-camera in the grounds is readily granted, yet we hear of instances in which applications by letter receive no attention, whilst other persons giving only a verbal assurance that their photographs were for private use only, have obtained permission without the least difficulty. The appointment of a single official photographer to an exhibition is bound to raise questions of difficulty, but we imagine that in thus making this appointment it is not the intention of the exhibition authorities to deny to visitors the opportunity of securing mementoes of the days spent in the picturesque grounds at Shepherd's Bush, and we are interested in finding it stated in "Photography" for Monday last that daily permits are to be issued at a charge of one shilling.

\* \* \*

#### **Photographic Measures of Star Colours.**

An interesting application of photography has been made by Messrs. J. A. Parkhurst and F. C. Jordan, who have attempted to obtain a photographic measure of the colour of a star by comparing the magnitudes of images obtained on ordinary plates sensitive only to blue and violet, with those given on plates sensitive to green and red. Pairs of plates were exposed regularly from 1904 to 1906 with the twenty-four inch reflector of the Yerkes Observatory, and it appears that the results have proved to be eminently satisfactory. By using a special filter screen with the iso plates, results were obtained that corresponded directly with the visual magnitudes, and by this method all errors due to the unsatisfactory nature of eye estimates were eliminated.

\* \* \*

#### **The Spectrum of Magnesium Oxide.**

Those who experiment with the spectrum have a vast field for exploration and frequently hit upon features that other workers seem to have missed. Mr. E. E. Brooks, of the Leicester Municipal Technical School, writes to "Nature" to the effect that there appears to be a well marked, though faint, fluting in the spectrum of magnesium oxide that has not been hitherto recorded, consisting of seven principal edges and several fainter lines. The wave-lengths of the principal edges are given as 4823, 4819, 4810, 4801, 4791, 4780, 4771. Two lines have been measured between 4771 and 4780, and five lines, possibly belonging to the system, between 4771 and 4731.

\* \* \*

#### **A Rival of the Camera.**

A complaint is made in some quarters that the vogue of the motor-car has trenchanted on ground occupied by photography as a pastime or hobby for the leisured and wealthy classes. If this is so it seems a curious fact, for while the photographer should find a car of the greatest possible value in getting around and about the country, and in carrying heavy apparatus to the most suitable hunting

grounds, the car owner who is not already a photographer should easily be tempted to become one, owing to obvious facilities that his car provides him with. The man who can afford a car can easily afford a camera, so that the matter of expense cannot very well affect the question. Altogether, we feel very doubtful if the complaint referred to is well founded. We should be rather inclined to the opinion that the possession of a car will inevitably sooner or later, to the acquisition of a camera, and motoring generally will lead to a much greater use of large size cameras.

#### **DIAGRAM LANTERN SLIDES.**

The worst slides usually to be seen in scientific lectures are the simple black and white line subjects. The difficulties in the way of producing fairly good line slides are great, yet we have often met with examples in which so-called "black" portions were so feeble as to be barely visible on the screen, while on the other hand, we have seen slides so badly fogged that the lines were nearly invisible from this cause alone. It has been suggested that the more scientific the lecture the worse are the slides, we should not like to describe this as a universal rule. The reason, no doubt, is that the slides are prepared hurriedly, probably on unsuitable plates and with a developer that happens to be most handy. The secret of success is certainly in the preparation of the negative, a good line negative is not a very difficult thing to make. Backed "process" plates must be used and hydroquinone with caustic soda and plenty of bromide is certainly the best developer. As for exposure, there is a considerable amount of latitude. When working by daylight we find the Wynne meter a very reliable guide if we give one-quarter of the full exposure that the meter suggests for the plate and stop in use. Another method that works very well is to use a stop of the same number as the Wynne speed of the plate in use, and expose for the time taken by the quarter-tint to darken. The diagrams should be on a large scale so that a fair amount of reduction, say one-third or one-fourth, is required, and development should give a dense black deposit with very slightly veiled lines. Development is carried far enough the lines can easily be cleared with a strong Farmer's reducer without damaging the black background representing the whites. Intensification may be necessary in some cases, while spotting is always required, but even this is easy, as it is only essential to block out the pinholes without paying any regard to their surroundings.

Professor Bryan, in "Nature," calls attention to the importance of good lantern slides in lectures, and emphasizes the fact that they should be of uniform density. To secure this quality in slides made from negatives of different densities he suggests the use of a simple form of photometer. A sheet of white cardboard is folded into the form of an isosceles prism or double inclined plane, the faces of which are illuminated by movable lights that can be placed at varying distances. If two negatives are placed side by side in front of the two faces of the prism, the lights can be adjusted until the negatives appear to be of equal density. From the distances of the lights the relative exposures can then be calculated. This appears to be a good and promising method, but we feel obliged to point out that the simplest method of producing uniform slides is to work under fixed conditions from negatives of uniform density, and there is not very much difficulty in securing uniform negatives in the case of such subjects as usually appear in scientific lectures. Systematic exposures—which we mean exposures adjusted by meter or by some definite method—and time development will, as a rule, produce negatives that vary very little in density, and therefore easily yield uniform prints.

# THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

## TWENTY-THIRD MEETING — IN BRUSSELS.

the weather, with just enough cool breeze to temper the shine, but without enough to make the sea-passage is to the weakest landsman, saw the opening of a con- that promises to be ever-memorable, and that is in many respects from previous meetings.

British (non-local) membership is a record, even at the writing, and several members will be added at the middle week. The local membership is phenomenally small—a in the reverse direction. The members from the British approached Brussels by many routes, the principal parties on Saturday, by Dover-Ostend and by Dover-Calais. and boats on the English side were crowded and late, n once the Belgian State Railway was reached, excellent le accommodation was found. This, and several other in which Belgium compared favourably with Britain, cks to the insular prejudices of many who were visiting erlands for the first time. Once in Brussels, they soon emselves into the gay, bright, open-air life of the capital, e is every prospect that sociability will eclipse photo- and give us another record—of the smallest number of ex- ver made at a convention. The Bois de Cambre in the e, and the Park of Wauxhall, with its fine open-air con- night, have proved most attractive and delightful rendez- nd the open-air café meals, on the borders of the busy have captivated all the visitors.

aturday, as the steamer reached Ostend, she ran almost e the Royal yacht of King Edward VII., and a number embers stayed in the port to see the annual festival of ing of the Waters. Those who went straight to Brussels e churches, the woods, the art-galleries, and the new laeken full of interest and variety on Sunday and Mon- ning.

official gathering on Monday, when members gathered ercle Artistique to meet each other and to "sign the t was found that the party was not only large, but also resentative, and included many old members who have r with the convention for some years.

oms are excellently adapted to the needs of the conven- n the first salon the Platinotype Company gives a fine of pictures by the best British and American workers; ond salon is a collection of local work—of which more nd in the lecture hall is a fine exhibition of forty-eight studies by Mr. Rudolf Dührkoop (who is a member this n exhibition and demonstrations of aerograph work by rles L. Burdick, and exhibits of pictures and apparatus ik, Ltd., by W. Watson and Sons, and by Carl Zeiss.

ollection of local pictures by members of the Association

Belge de Photographie is worthy of all praise, and is far ahead of the shows of local work usually arranged in Britain. The good things are far too numerous to be specified in the space at our disposal, but almost every exhibitor was well represented. Some of them are already known at the R.P.S. Exhibition and the Photographic Salon, and we think that more than one of the others should be induced to exhibit in England.

At the reception on Monday afternoon, H.R.H. Prince Albert of Belgium, the Président d'Honneur of the Convention, attended and welcomed the principal visitors, but was obliged to leave before the formal business began.

In the absence of Mr. Alfred Watkins, the retiring president, who was detained in England by illness, Mr. E. J. Humphery took the chair and introduced Sir E. Cecil Hertslet, this year's president. They were supported on the platform by Messrs. F. A. Bridge (hon. sec.), C. H. Bothamley and F. de P. Cembrano (past presidents), Commandant van Bever (president of the Association Belge), M. Ch. Puttemans (vice-president), and M. Vanderkindere (hon. local sec.).

Sir E. Cecil Hertslet spoke of the peculiarly interesting circumstances of this first convention outside the United Kingdom, and said that nowhere could it have visited a more hospitable people. He referred to the splendid collections of the old and the modern masters of painting to be found in Belgium and of their influence upon photographers, as well as upon all other artists. Speaking of the great influence of the Association Belge, with its headquarters in Brussels and its branches at Malines, Ghent, Liège, Namur, and Mons, and of its excellent monthly "Bulletin," he introduced tributes to two Belgian workers on the technical side—Von Monckhoven and Josef Maes—and to the British photographic Press, which he described as the most influential in the world. In reviewing the past year, he referred to the loss of Mr. John Stuart, a past president, and Mr. A. Horsley Hinton, a member of Council of the Convention. He then sketched the recent progress of photography in picture-making in record work, and in technical progress, with special reference to the Autochrome and to the Donisthorpe processes.

The vote of thanks was proposed by Mr. C. H. Bothamley and seconded by Mr. F. de P. Cembrano.

Dr. W. Scheffer read a paper and showed many excellent slides to illustrate the structure of the Autochrome plate; and Captain Harfeld explained a most interesting collection of slides of the Far East.

The conversazione at night was distinctly informal, but none the less enjoyable. Business: Renewing old friendships, and enjoying the fine music provided by the evening concert in the Wauxhall Park adjoining the rooms of the Cercle Artistique.

## THE PRESIDENT'S ADDRESS.

Following was the address given by the President of the Convention, Sir E. Cecil Hertslet:—

very appreciative of the honour which has been conferred by my election to the Presidential chair of the Photographic Convention. The circumstances under which we have met are peculiarly interesting, for the Convention has made departure, and, for the first time in its history, has deter- hold its annual conference beyond the limits of the United Kingdom. Since the Photographic Convention was founded in 1886, advancement of photography and to afford opportunities for intercourse and exchange of ideas among those interested in it, its annual meetings have never failed to be attended with success and enjoyment. The Convention has usually been held in England, but on four occasions it has visited Scotland, and on two occasions Ireland. We are now assembled for the first time

on foreign soil in order to hold our conference at Brussels by the invitation of the Association Belge de Photographie. It would not be possible for us to meet in any foreign country where we should receive a more friendly and hospitable reception than that which is about to be given to us in Belgium, and, in addressing you to-day, on the occasion of the formal opening of the Convention, I do not hesitate to say that when you return to your homes you will carry back with you the most agreeable remembrance of the welcome which you are certain to receive from the Belgian people.

You will have in Belgium the opportunity of seeing the very finest examples of Flemish art: in Antwerp Cathedral, Rubens' "Descent from the Cross"; at the Antwerp Picture Gallery the best and most noted works of Quentin Matsys, Rubens, and Van Dyck; in

Ghent Cathedral, Van Eyck's "Adoration of the Lamb"; and at Brussels and Malines other notable works by the great Flemish painters. Besides the pictures of the Old Masters, you will see both at Brussels and Antwerp excellent examples of landscape, seascape, and portraiture by modern painters. You will find yourselves, therefore, in the midst of artistic surroundings which must necessarily appeal to those among you who aim at the attainment of the art of picture-making by photography.

In Belgium there are many enthusiastic adherents of every branch of photography—men of science, amateurs, and professional photographers—and, as is happily the case among ourselves, a complete understanding exists between those interested in the several branches of the art. There are no divisions or distinctions, and all persons connected with photography associate in the same societies, and work harmoniously together.

Belgium has not produced many pioneers in photographic science. The best-known Belgian inventor is Van Monkhoven, who some years ago published an improved method of making dry plates, which was thought highly of at the time, but this was, of course, when dry plates were in their infancy. Mr. Joseph Maes, one of the veterans of the photographic world, is President of the Antwerp section of the Association Belge, and is still an active worker.

Photographic societies in Belgium are but few in number, by far the most important and influential of them being the Association Belge de Photographie, at whose invitation the Convention is now being held in Belgium. The Association Belge was founded in 1874, and is, therefore, quite venerable compared with the Photographic Convention, which came into existence only twelve years later. It enjoys the special patronage of his Majesty the King of the Belgians, and his Royal Highness Prince Albert is its "Président d'Honneur." This Society overshadows the smaller Belgian societies far more completely than the Royal Photographic Society dominates other societies in the United Kingdom. It has a membership of about 600, and its sphere of action comprises the whole of Belgium. The Society's headquarters are at Brussels, but it is divided into sections which are located at Antwerp, Ghent, Liège, Namur, Verviers, and Mons. Each section is managed by a local committee, and although subordinate to the central administration at Brussels, enjoys a considerable amount of autonomy. This system of allowing a certain freedom to the local branches has assured to the Association Belge the preponderance to which I have already referred, and for twenty years it was the only photographic society in the whole of Belgium. The Association organises from time to time photographic exhibitions to which our foremost British workers have frequently contributed, and photographs by its members are often seen on the walls of the Royal Photographic Society's Exhibition and of the Photographic Salon. The monthly Bulletin of the Association is an attractive publication, illustrated with artistic reproductions of some of the best work of the members of the Association. The Bulletin contains articles of general interest, many of which are translated from the British photographic Press, while the minutes of the proceedings of the Association also find a place in it, but one that is secondary only. The Bulletin of the Association Belge compares very favourably with the "Photographic Journal," the monthly publication of the Royal Photographic Society. There is a certain dullness overshadowing the monthly publication of our premier photographic society, and, without departing from the principle of restricting its contents so far as possible to the Society's work, the Royal Photographic Society might perhaps consider whether some of the more attractive features of the monthly Bulletin of the Association Belge might not with advantage be incorporated into its journal. A little additional brightness and vigour in the pages of the "Photographic Journal" would, I feel confident, be generally welcomed by the members of the Royal Photographic Society.

But if the appearance of the "Photographic Journal" compares somewhat unfavourably with its Belgian contemporary, the same criticism does not apply to the British photographic Press. There are very few photographic newspapers or other similar publications in Belgium, and the British Press has nothing to learn from any of them. Indeed, it may be stated, without fear of contradiction, that in no country in the world is there a photographic Press which can be compared to our own, whether from the point of view of the letterpress or of the artistic pictures which are reproduced therein. Our British Press has been recently strengthened,

and its influence concentrated, by the amalgamation of the "Graphic News" with the "Amateur Photographer," and of "The Photo" with "Photography," whilst the "British Journal of Photography" continues to maintain the high standard for which it has always been renowned.

The photographic societies in Belgium, apart from the Association Belge, are of no great importance, but mention must be made of the institution known as the International Institute of Photography, which has already rendered useful services in arranging and publishing photographic records, and which is destined in the future to render even greater utility. The object of this institute is to centralise everything relating to photographic records, and to centralise the office all photographic documents, so that they may be readily accessible to the public. The International Institute of Photography is attached to the International Institute of Bibliography, of which it forms a section. It possesses a very valuable collection of documents of all kinds, which is continually being added to. The documents, which are classified methodically, are placed gratuitously at the disposal of all persons who may be desirous of consulting them, and who may wish to avail themselves of the services of the institute in connection with any work on which they may be engaged. I recently visited this institute, and I found that the documents which already number 100,000, are systematically arranged, and that, owing to the excellence of its organisation, it is possible, without loss of time, to refer to any particular subject on which information may be required. I would advise members of the Convention, and especially those who are interested in library work, to avail themselves of a courteous invitation which has been received that they should visit the institute before they leave Brussels.

In this connection I heartily commend to your notice the work which is being accomplished in our own country by the National Photographic Record Association, under the presidency of Benjamin Stone, M.P., and by the "Amateur Photographer," which is urging its readers to make records of interest and antiquity. The records are likely to be destroyed to make way for modern improvements and alterations. In Belgium the changes looming in the future have continued extension of the old Flemish cities are very great. Antwerp, for instance, the moated fortifications, which form perhaps the best example in Europe of nineteenth-century military architecture, will shortly be demolished, and three adjacent villages with their ancient parish churches, are doomed to disappear together to make room for the extension of the port of Antwerp. Elsewhere old houses, narrow streets, and the quaint corners of the old towns are disappearing in all directions. One of the most useful works of the photographer will be to preserve for posterity a true record of the ancient churches, streets, and houses of interest.

There is one other duty which I desire to take this opportunity of impressing upon you, and that is to place all your influence on the side of those who in Parliament and elsewhere are endeavouring to put a stop to the disfigurement of our British landscapes by unsightly advertisements which mar our country fields, and are particularly conspicuous at the side of so many of our railway routes. The members attending this convention have homes in all parts of the United Kingdom, and our united voice ought to make itself felt in assisting the efforts which are being made to effect the removal of this blemish from the scenery of our country. The nuisance is especially annoying to photographers, as we are, with artists' licence, eliminate these undesirable adjuncts which detract from a photographic picture.

The subject before us this afternoon is so wide—and, indeed, inexhaustible—that it is only possible for me to give utterance to a few thoughts for your consideration. Photography affords a unique combination of both science and art. It is not only a science in itself, but it is the means of rendering most valuable assistance to other sister sciences, particularly to astronomy and medicine. At the same time, I defy unprejudiced persons who have visited the great pictorial exhibitions to assert that photography is not an art, or to deny that the best results are obtained by those of us who have eyes to see and minds to appreciate the beauties of the scenes which surround us.

I also desire to bear testimony to the educational usefulness of photography, and particularly to that branch of it which deals with the production of lantern slides. Due recognition is not always given to the assistance rendered by photography in producing

to education. I was recently present at lectures given before the Royal Geographical Society of Antwerp by two of our great British explorers, Lieutenant Boyd Alexander, who described his journey across Africa from the Niger, by way of Lake Tchad, to the Nile, and Captain R. F. Scott, who has succeeded in getting further to the South Pole than any other explorer. The interest of these lectures was trebled by their slides, and no one who was present could forget the photograph taken by Captain Scott at the furthest point south to which he attained, in which were clearly seen the snow-covered mountains which screen the South Pole from the traveller who would venture to approach it across the Antarctic ice.

There is one interesting historical fact which I should like to mention. At the time of the war between Belgium and Holland in 1830, when the Belgian people were fighting for their independence, Monsieur de Hochepeid Larpent, British Consul at Antwerp, observed, with concern, that the shells of the besieging force were menacing the safety of the tower of Antwerp Cathedral, the admiration to-day of the photographic world. My predecessor visited the camp of the besieging forces, accompanied by one of his colleagues, and by some of the notabilities of the city, and asked him to turn the fire of his cannons in another direction. This request was gratefully acceded to, and my predecessor was in this way the principal means of saving for Belgium its chief artistic glory, the Cathedral spire of Antwerp.

Turning, now, to the advancement of photography during the past century, it is certain that the most interesting and important photographic event that has occurred since the last meeting of the Convention is the introduction of the Autochrome plate, and the great advance which has been made in the art of photography in natural colours. Most of us have had the opportunity of viewing some of the results attained by this process, either at the last exhibition of the Royal Photographic Society, at the exhibition by the Society of our photographers recently held at the office of the "British Journal of Photography," or at the special exhibition organised by the Association Belge de Photographie, held last winter. The excellence in merit and artistic beauty of these photographs in natural colours, and the fact that the colours can only be seen by transmitted light, convey the irresistible impression that we are really on the threshold of the colour photography of the future. It seems at the present moment to be standing very much in the same position where Daguerre and Niepce stood when those distinguished pioneers first made known to the world their ability to produce photographic positives, and when each exposure gave only one resulting picture. We await with eager anticipation the advent of the Fox-Talbot of colour photography, the discoverer of a system, the means of which we may be able to produce a negative from which positives in natural colours can be duplicated. With this thought must abstain from further consideration of the progress in colour photography of which the Autochrome plate is such an interesting example. The subject has been dealt with exhaustively in the photographic Press, and we are shortly to have the advantage of reading a paper on the structure of the Autochrome plate by Dr. Scheffer.

I must make special mention of the method recently invented by Frank Donisthorpe, as that process is a new departure from the ordinary printing processes, the printing being independent of the action of light. The operation is briefly as follows: The negative to be printed from is immersed for five minutes in a hardening bath, and is then rinsed for two minutes, and placed in a strong dye solution for another five minutes. After being taken out of the dye solution and again washed, the negative is laid film upwards on a piece of glass, while a piece of gelatinised paper which has been soaked in the dye solution for two minutes is laid face downwards on the negative, the two being pressed together. After a few minutes the paper can be easily pulled off. It is then dipped for a moment in methylated spirit, and, after being blotted, the print will be dry in five minutes, and is finished. A fresh immersion for about half a minute in the dye solution makes the negative ready to have another print taken from it in the same manner. In fact, any number of prints can be taken from a negative after one hardening bath has been used. The process is one which has the advantage of both cheapness and simplicity, and, if ordinary care is taken in the selection of the negative, the resulting prints will be permanent. It is a process which is very useful when a large number of prints are required

from a single negative, but it does not appear as though it would be likely to be used by pictorial photographers, much of the beauty of whose work depends on a careful manipulation of the printing with a view to bringing out the high-lights and protecting the details in the shadows.

Modifications and improvements continue to be made in the ordinary printing methods, particularly in those that have the carbon process for their basis.

Since the last meeting of the Convention we have to deplore the deaths of some of our best-known fellow-workers: Mr. John Stuart, who was President on the occasion of the second visit of the Convention to Glasgow in 1898, died during the Hereford Convention week. Mr. Stuart, who was one of the first members of the Convention, was an eminent practical professional photographer, and he is sincerely mourned by a large circle of friends.

We have also to record with deep regret the death of Mr. Horsley Hinton, one of our foremost pictorial photographers, and a member of the Council of this Convention. Mr. Hinton has left a gap in the photographic world which it will be hard indeed to fill. For many years his work has been familiar to us all, and the interest recently shown by so large an attendance of the public to view the examples of his photographs at the special exhibition held a short time ago in the rooms of the Royal Photographic Society is a proof that the beauty, delicacy, and good taste of his photographic work are very highly appreciated. Mr. Hinton, who was an indefatigable worker, not only as a practical photographer but as Editor of the "Amateur Photographer," and photographic correspondent of some of the great London daily newspapers, and whose premature death may have been due in a measure to his having overtaxed his strength, has undoubtedly exercised a considerable influence upon the pictorial photography of the end of the last and the beginning of the present century; there can be no doubt that that influence, which was largely due to individual and personal effort, was altogether a beneficial one.

I trust, ladies and gentlemen, that you will carry back with you to your homes many beautiful photographic pictures of Belgian life, of the architectural riches of Brussels, and of the interesting ecclesiastical and municipal buildings which form the glory of the ancient Flemish cities of Antwerp, Ghent, and Malines. To us whose eyes are opened to the beauties of photographic art, it seems strange that the public should sometimes so completely fail to realise what we aim at when we attempt to make our pictures by photography. For instance, the "Daily Mail," in giving a description of the opening of the Druce tomb in the Highgate Cemetery in December, 1907, wrote as follows:—"Two planks were laid across the tomb, and a photographic camera was brought and placed in position to take a picture of the caskets as they lay, dust and grime included." It is depressing to reflect that in the minds of some of our fellow-countrymen such a gruesome subject as this could possibly form a photographic "picture." On the other hand the photographic artist will attempt, and often unsuccessfully, to make pictures out of the most difficult and unpromising material. Some of the finest lantern slides that I have ever been privileged to see were representations by M. Marissiaux, a Belgian photographer, of life and work in the coal mines of the district of Liège. These photographs illustrated the ordinary daily life in the mines, not only above the surface, but in the depths of the mines themselves. The figures were carefully selected and correctly posed, and the contrasts of light and shade were admirable.

If, ladies and gentlemen, you determine to face in a like manner the difficulties which confront you, you will take away with you from Belgium artistic pictures which will be a credit to you and to British photography in general.

As President of the Convention, I desire to express, in my own name, as well as in that of all the members, our sincere thanks to his Royal Highness Prince Albert of Belgium for the honour conferred upon the Convention by his acceptance of the office of our "Président d'Honneur." We are well aware of the interest which Prince Albert takes in the advancement of photography, and we greatly appreciate his Royal Highness's courteous action in acceding to our request that he should allow his name to be associated with the Brussels meeting of the Convention.

In conclusion, I must not omit to mention the valuable assistance which has been received from Commandant van Bever, the President of the Association Belge de Photographie, to Monsieur Vanderkin-

dere, and the Council of the Association Belge, in making such excellent arrangements for the busy week which lies before us. Last, not least, I must pay a tribute to our honorary secretary and treasurer, Mr. Bridge, who has been indefatigable in his endeavours

to secure the success of the Brussels week. This is the eleventh annual meeting of the Convention which has been marshalled by Mr. Bridge, and, as time goes on, his services to the Convention become more and more invaluable.

## ON COPYING FADED AND DETERIORATED PICTURES.

### II.

#### Faded Paper Prints.

In the previous article the copying of daguerreotypes and glass positives that had suffered by the ravages of time, or from other injury, was dealt with, and it was there pointed out that professional portraitists, by making a special line in that class of work, could very frequently turn it to a very profitable account.

Probably the larger proportion of this class of business that comes to the professional at the present time is in the form of paper photographs in a more or less advanced stage of decay, such as *cartes de visite* that, with age, have passed into the sere and yellow leaf. These pictures, by reason of their yellow colour, very often appear most unpromising things to copy, but they are really not so when one sets the right way about the work. These old paper pictures, as a rule, are not really faded in the true sense of the term. The lights may have become strongly yellowed by age, but usually all the detail is there, though somewhat buried in the general discoloration of the paper. If the yellowness were removed, the picture would be much improved in appearance, as well as for copying. This can readily be done, if it is a gold-toned picture, by simply immersing it in a weak solution of bichloride of mercury until the yellowness disappears. This treatment will remove the yellowness and leave the picture bright and clear, though of a somewhat warmer tone. A word of caution may, however, be given here. We have assumed that the print has been toned with gold, as all the old C.D.V.s were, but, if that were not the case, the mercurial treatment would remove the whole of the image and leave only bare paper; so that pictures only that are known to have been thoroughly toned with gold should be submitted to this kind of renovation. Even if the picture has been toned with gold, no detail that has actually faded out will be restored. Different methods of restoring faded photographs have, from time to time, been published. I have tried most of them, but none have proved, in my hands, of any practical value, at least for copying. Indeed, the copies made from these "restored" pictures have all been inferior to those I could have obtained from the pictures in their original state.

#### Avoiding Grain in the Copy

At different times I have read very elaborate methods given for copying paper pictures so as to avoid the "flannelly" or granular appearance the copies frequently present. The greater portion of these articles have evidently been written by those who have had but little practical experience in this kind of work. Most of it has been written under an entire misconception of the conditions obtaining. The writers have seemed to have assumed that the granularity is due to the unevenness of the surface of the paper; whereas it certainly is not. If it were, then heavily rolling the picture, so as to make the surface quite flat, would get over the trouble; whereas it does not; indeed, in some instances it appears to increase it. On the assumption that the woolliness proceeds from the unevenness of the surface of the paper, it is often advised that the picture be copied in a direct front light, and even a reflector of white paper placed below it to soften the shadows supposed to be cast from the paper fibres. Now, these are really about the worst con-

ditions under which a faded albumen print can be copied. The woolliness does not proceed from any unevenness in the surface, but from reflections from the glossy fibres of the paper, and it is these that have to be avoided in order to obtain a satisfactory reproduction. In the previous article it was pointed out that as the angle of incidence of the light falls on the object equals that of its reflection, the print should always be illumined at such an angle that any reflection there may be should be away from the lens, and not into it as is the case when a direct front light is employed in the copying.

#### Use a Side-light.

The best light in which to copy a paper picture, such as are now supposed to be dealing with, is a strong side one. This is diametrically opposed to much that has been said on the subject, but—the "proof of the pudding," etc. Let any one who is in doubt on the point, when he has a picture of this kind reproduced, first make a negative of it with a direct front light, and then another where the picture is lighted direct from the side, with all front light stopped off. On comparing the two he will be in no two minds on the subject. The point can easily be demonstrated without the exposure of plates in the camera. Let any one examine a paper print, such as we are now considering, in an ordinary room, standing with his back to the window, and holding the picture before him so that it is only lightly by direct front light. He will here see the granularity very strongly pronounced. Then let him turn sideways, and hold the picture at the side of the window, so that it is lighted only with a strong side light. It will then be noticed that the granularity has disappeared, and the image is quite free from it. This simple experiment should at once convince any one that a direct side light is the best in which to copy albumen prints.

When enlarged copies of this class of old photograph are required for finishing in monochrome or colour—and they are required much use without—it goes without saying that when the reproduction is of the woolly kind, a great deal more work is entailed in the finishing than if it were otherwise. Therefore it behooves the copyist to go to some extra trouble to get the best possible result to begin with. A very woolly enlargement, unless it is of a size that can be boldly dealt with, entails a lot of niggling work that may generally be avoided, if the one who makes uses skill and judgment in doing his work.

A method of avoiding the granularity was suggested many years ago, and may here be mentioned. The picture is removed from its mount and then mounted, with water, in optical contact with a glass plate. It is then copied through the glass. But in practice it will soon be found that this does not improve matters; some have even affirmed that it makes them worse. Certainly, in my hands, it has proved no improvement at all.

With regard to the plates most useful for our present purpose, theory tells us that orthochromatic ones are the best, but in actual practice I have found no actual advantage in them. I always use those I happen to be working with at the time. One point should have special attention, and that is that in all cases over-exposure should be avoided, as that tends to give mealiness of image.

WM. MICHELL.

## HINTS ON CHILD PHOTOGRAPHY.

(A Paper read before the Twelfth Annual Meeting of the Photographers' Association of Wisconsin.)

The subject that I have chosen for my address, that of child photography, is one of unlimited possibilities, touching, as it does, that most important branch of our profession, the photographing of the little ones. To my way of thinking there are no other subjects that we come in contact with which offer as great returns, financially and otherwise, as do these little friends of ours. There are many of our brother photographers, however, who, while seemingly realising this, are ill disposed to give the matter scant attention. Why, it is hard to say. Many claim that they have no success with the little ones; claim all kinds of excuses for failure in this line; at the majority, of course, blame the children. Candidly, I cannot agree with my brother photographers who seek to take the blame of their failures from themselves and put it where it does not belong; for, to me, there are no other subjects that we have who are as easily photographed as the children, provided we go about it in the right way.

### Toys and Plates.

Naturally, the question arises, "What is the right way?" Of course, in child photography there can be no "cut and dried" programme to follow: we have to adapt ourselves to the conditions as they arise, and be guided by our own and that we know of the experiences of others. Personally, I have always found it a good idea to become as well acquainted as possible with our little friends while they are still in the reception-room. Naturally, being amid strange surroundings, they are quite apt to feel somewhat diffident and bashful. On entering the operating-room, try to make them feel entirely at home, as, unless they do, it is almost useless to go further. You may take a little time, but you will find it time well spent, for you will never regret it. One of the best and quickest methods for gaining their confidence is by the use of toys. I always keep my studio well stocked with these; not in sight, but in a large cupboard in one corner of the room. I have found it the best policy to use but one toy at a time, three or four things will tend to confuse the child, and so make your work correspondingly difficult. When the little ones commence to enjoy themselves and forget their surroundings, you can commence to expose your plates, and don't be afraid that you are going to use too many. Make anywhere from five up to an indefinite number, judging by the size of your customer's pocket-book, although this is not always a safe rule to follow. In many cases it is not the people with the most money that spend the most.

In making a large number of poses you will find that your selection of toys will help you greatly, as you can make as many sittings as you wish and still have them all entirely different. Let the little ones play ball, build houses with blocks, have a dinner-party, or anything else that they enjoy, and photograph them while they are doing it. You will find that the result will please you; and, what is more to the point, it will please your customer. When you have made the full-length pictures that you want, sit the child on the floor and make one or two large bust heads, thus giving you a still more varied assortment.

Now you are ready to show proofs. Select the best ones; put them in a row, with the bust picture in the centre, and draw the attention of your customer to the beauty of the entire set for framing purposes. Try this, and you will be surprised to find the number of these rows you can sell, in addition to a single dozen single photographs, and your four or five dollar order will increase to fifteen or twenty before you know it.

### How to Dispense with Re-focussing.

To return to the operating-room. Some people have asked me what I consider the most useful and valuable toy to use

in photographing children. In answer to this question, I think that I use an ordinary rubber ball more than anything else. I have yet to find the child that I cannot interest in this little plaything. Just roll it across the floor—not necessarily at the child itself, but, for instance, up on the background, where it will roll back of its own accord. Do this a couple of times, and almost invariably the child will follow it. It seems to have the same fascination for them that a string has for a cat. When you have awakened the child's interest in this manner, ask him to throw the ball to you, and in a moment you will have a full-fledged ball-game on your hands.

Now comes the next step. Tell the little one that in order to play ball right you must have a base, and he or she must stand on it when they throw the ball. (Of course, you are using a light background with a floor-cloth, or if you are not, you should be.) Take a pencil and lightly trace a circle on it, about a foot in diameter. Then get the child to stand on the base and focus the camera while he is there. This will solve the focussing question for you, as, no matter how often he leaves the spot, bring him back and he is in focus again.

You can now go ahead with the ball-game if you wish. Take the ball yourself, have Johnny on the base, and count three, throwing the ball to him on the third count. He will hold his hands outstretched, and a look of intense interest and expectation will spread over his face. That's what you want, so press the bulb. Then let him throw the ball to you. When he draws his arm back, make another exposure; and so on. You can make a dozen poses this way without re-focussing, if you wish. Then, too, when the ball-game is over he is thoroughly livened up and ready to play with anything else you may show him.

One thing that I wish to call your attention to is a very simple little trick that I use a great deal to attract the attention of children. It's rather hard to explain it without demonstrating it at the same time, so I will do both. First take a copper cent, or, if you haven't that, a twenty-dollar gold piece will answer just as well. Moisten it, when the child isn't looking, and place it upon your forehead, and make it stick there. Tell it to come down—it will come. Do this a couple of times, and then have Mary or Johnny to tell it to come down. When it comes, it will usually bring a smile with it.

By the way, make your baby-pictures with laughing faces if you can. People admire a sweet expression; but, nevertheless, they usually say, "I want baby laughing, just as he does at home." And it is "up to you" to take him that way or lose your reputation. That reminds me of a group I once had in the studio—three children and a dog. The instructions were, to photograph the two younger children laughing, the older one sober, and the dog's ears standing up straight. Now, I am willing to try almost anything, so I tried to photograph this group. However, I failed to "make good." I could get the children all right, but, judging from his actions somebody must have glued the dog's ears down, and I couldn't "get a rise out of them."

### Backgrounds.

Now, a word about backgrounds. I believe that in ninety-nine cases out of a hundred, a white, or at least a light, background is the most desirable one to use, as it gives a light and delicate effect that greatly enhances the beauty of any child's photograph. Personally, I use a blue-white ground for my platinum work, with a slight cloud effect added to the finished print. For the cheaper work I generally use a light ground with a suggestion of a curtain painted on it. This, I find, gives a much more artistic print than a dead white ground with nothing to relieve the figure.

In conclusion, I will say that while child photography, successfully done, requires both time and study, it is still a paying branch of our profession in which to specialise. Build up a name for yourself as a good child photographer, and the rest of the people will come as a matter of course. Make up your mind that you can do it, and you will find that, like

everything else in life, it is just what you make of it, and not especially difficult after all. Push your children's work the front—put out specially nice displays in your showcases exercise all the tact and patience that you have, and there is no question but that you can soon build up a name for yourself as a successful child photographer. L. D. CLAPP.

## THE PRICE OF THE PHOTOGRAPH—AND THE COST.

[The season of photographic conventions in America being just over, our contemporaries in the United States are full of the papers read before these meetings—or business conferences, as they most often are—in various parts of the country. The following paper, which the author himself calls "The Business Art of Getting the Big Round Dollar," was read before the Photographers' Association of Illinois, and may be commended as a vigorous version of a sermon which is constantly being preached to photographers, and needed, apparently, as much in America as in the United Kingdom.—Eds. "B.J."]

I HAVE been attending photographic conventions for a number of years, and I have never attended one where I did not receive a benefit, but the lectures in each session have always been on the line of Art, or what constitutes an artistic picture and how to produce it, with part of the time being taken up discussing whether we are entitled to be called artists. Now what difference does it make to you or me whether we are entitled to be called artists or not, so long as our patrons consider our productions of a high class and are willing to pay for them? Now the art I am going to talk on is the business art of getting the big round dollar, a branch that has been neglected heretofore at our conventions. To begin with, we will take a little trip through the country and stop at every town of any size and inquire as to who are the leading citizens, and we will go from the Pacific to the Atlantic, and in no instance will a photographer's name be mentioned as one of the leading citizens, while all other occupations will be represented. Now, why is this? The only conclusion that I can draw is that we have spent our lives in learning how to make a picture, and not the dollar. Now there must be something wrong in some way with our methods, and the conclusion I have come to is that we are controlled by precedent. I would like to ask if there is any one present who can tell me what it costs him to produce a dozen pictures? (No response.) Well, if you don't know what it costs you to produce an article, how are you going to put a selling price on it? I wish each and every one of you will go home and find out just what it costs you per dozen, and report at next convention, for I am satisfied that after figuring the cost of production you will cut out all pictures that you are making for less than cost. You must take a year's business for an average. Put down your rent, what you paid out for help, taxes, heating, incidentals, stock bills, then add about 5 per cent. for wear and tear, add up and divide total by number of dozen pictures you made during the year, and you will have the exact cost per dozen. Then the different sizes can be figured on basis of difference of cost of material that goes in the picture.

### Cost of Production

To illustrate: a former friend of mine came into my studio (and being an amateur of considerable experience and away above the average intelligence), said he wanted to have some pictures taken, and asked me what he ought to have. I threw out a picture and told him that was what he wanted. He asked me what they were worth. I told him only twenty dollars per dozen. He says: "Ye Gods! you ought to get rich." I told him if I made as large a profit on those pictures as he did on his corn, I would. He said: "What are you talking about? It doesn't cost you over two dollars a dozen to make these." "Well, now," says I, "let's figure a little. How much land will a bushel of corn plant?" "About five acres." "Well, you will raise about 50 bushels per acre?" "Yes." "And 50

bushels at 50 cents per bushel is \$25?" "Yes." "Cost of seed corn 10 cents, profit \$24.90." "Well, you must consider cost of my land." "No, you don't consider the cost of studio." "Then you must consider my hired hands." "No, don't consider the cost of my help." "Then look at my horses and implements." "You must not consider your horses and implements; you don't consider my implements." "Well, look at my time." "You must not consider your time; you don't consider my time. You only consider the cost of plates, paper, folders, or, in other words, the seed corn in my production; if I charged in proportion to your profit on corn I would give you four hundred dollars per dozen, while I am only asking you twenty." "Well, go ahead and make them; you have the best of the argument."

Another time a lady came into my studio and made an engagement for a sitting, saying she wanted some nice photographs to give her special friends, she having had a dozen finished the week before by her home photographer, but they were, as she said, only cheap pictures, being \$3 pictures, good enough to give to ordinary friends, but not good enough for special friends. When she came in for her sitting she brought one of those cheap pictures with her, and I want to tell you they were elegant pictures; fine lighting, beautifully posed, well developed, and nicely toned, only they were mounted on a cheap card, and it made me hump myself to get one as good and, by finishing nicely and mounting in nice folders, she paid me \$20 per dozen, and was thoroughly satisfied, and I preserved them for her particular friends with considerable pleasure, having confidence in quality because she paid a good price. This goes to show that a customer will not place a higher value on your productions than the man that makes them. So be satisfied and produce the value and charge for it if you want to be satisfied, but one without the other is never appreciated. It costs me \$3.34 per dozen to produce pictures, and the cheapest picture I make is \$4, and I make only a few of them, but I can see I never make a dozen for less than cost. And after I figure the cost of production I am satisfied that you will cut out all pictures that you are making for less than cost; then your bank account will begin to grow, and you will feel more like a business man.

### Babies, Lovers, and Old People.

I would also suggest that when you go home you call a meeting of all your competitors and see them personally, lay out a plan before them and show them where they are making pictures for less than cost of production, then establish a minimum price and all agree not to make any more work for less than cost. If you can, I would suggest that all photographers in the same town (county, if possible) meet once a month and talk over business. We all have our dull times, and when it is very easy to think the other fellow is doing all

ness. So to stem the tide the first thought that comes to us is to cut prices—the very worst thing we could do, for it is us in the estimation of the people, and they think that it doesn't cost anything to produce pictures or we wouldn't cut prices so. Now, there are staples in the picture business as in the grocery business. The staples of the picture business are babies, lovers, and age, for every baby that comes to be photographed, and when a young man falls in love he must have his girl's picture, the young lady must have the picture of her man's; and time waits for none, so we must have the picture of the old folks, and that class of photographs are as

staple as sugar. Then the business of the photographer depends on his ability to produce quality and his mixing quality, so don't shut yourself up when not at work, but be a man among men. Join organisations and get acquainted with as many of the good people as you can, and never presume superiority to any one, but consider yourself as good as the best. Another point I want to mention: Never attempt to quote prices on the street; tell them you have all kinds of prices, according to quality, and they must come in and judge for themselves; then when you get them in your studio if you don't land them it's your fault.

R. H. MANN.

## THE CHEMISTRY AND PHYSICS OF COLLOIDS.

### IV.

The following is the abridged text of the concluding lecture by Dr. S. E. Sheppard at the L.C.C. School of Photo-engraving, Lithography, Bolt Court, London, E.C. The previous lectures have been reported in the Journal for June 12, 19, and 26, 1908. —Eds. "B.J."]

well-known investigations of Carey Lea on the coloured silver halides, prepared by the partial reduction of normal silver halides, led him to the view that these consisted of mixtures of silver halide with normal halide, of the nature of lakes or, as we may term them, adsorption-compounds. Furthermore, he was of the opinion that both the printed-out image and the so-called latent image were identical in composition. The view that a sub-salt was combined in this manner with the normal silver halide was taken because of the resistance to bleaching by these silver halides in oxidising solutions which destroy metallic silver. Whether it was silver or sub-salt combined, the properties of the halide were greatly changed (both the colour and the light-sensitiveness), even in the case of quantities small to be analysed. One method of obtaining "photo-lakes" deserves especial mention; it consists in heating silver precipitated silver chloride with finely divided silver in aqueous suspension. On treatment with nitric acid a red silver halide is obtained. Lea was of the opinion that it could reduce normal halide to the sub-salt  $Ag + AgCl$ .

Lüppo-Cramer has carefully repeated these experiments and comes to a different conclusion. He prepared hydrocolloidal solutions of silver bromide and silver iodide in these in different proportions. No colour change was observed, and the silver was entirely dissolved out from the solution. The result was quite different if the mixture was coagulated or precipitated, as with sulphuric acid. The precipitate on treatment with nitric acid loses silver till a certain colour is reached, which is not discharged. The colour change always occurs on coagulation by electrolytes. The silver is removed from the "solution," not from the coagulum. "Insoluble metallic" silver no combination is obtained. These grounds Lüppo-Cramer concludes that no chemical compound of the nature of a sub-salt, but simply an "adsorption-compound" of silver and normal halide, is formed. This is further supported by the fact that the silver halides can be reduced or dyed with other colloidal metals, as gold, platinum. On the other hand, Biltz has shown that mordanted wool on freshly precipitated alumina form coloured "lakes" with colloidal gold, and with "collargol," so that the assumption of an adsorption-compound appears unnecessary. The formation of "photo-lakes" by the simultaneous flocking out of the colloidal silver components ( $AgX + Ag$ ) by electrolytes cannot be considered as a chemical reduction, nor anything but the formation of an adsorption-compound of silver halide and silver.

#### Influence of Dilution or Size of Grain

The conception that the "latent image" consists also of an adsorption-compound of silver with the unaltered halide readily

explains a large number of peculiarities. We have seen that the resistance to oxidation does not require the assumption of a sub-salt. In particular, the difference of behaviour of fast and slow plates, or generally of different makes, in this respect, can be satisfactorily discussed. Whereas the "photo-haloids" in the hydrosol state are not resistant to destruction by oxidation, this resistance increases with the size of the particles; in other words, the more dilute the mixture is with respect to silver, the greater the resisting power of the latter. A variety of recent researches, among which I may cite those of Schaum and Bellach, of Dr. Mees and myself, those of Dr. Scheffer, and Lüppo-Cramer's, on the influence of the micro-structure of the photographic film on the reactions occurring in it, have shown that the "grain" is the fundamental unit which has to be considered. From the adsorption theory we see that in large grains with small proportion of silver the resistance of the latter will be greater than in small grains containing a larger proportion. The same reasoning leads to an explanation of the difference in behaviour with retarded development of the lesser exposed and more exposed portions of the plate. Furthermore, according to Lüppo-Cramer, the selective action of persulphate on the high-lights of the negative is to be referred to the greater content of these, after fixation, in silver.

#### The Image After Fixation.

The image after fixation has usually been conceived as consisting of pure silver (save for organic stain). The rôle of adsorbed oxidised material we will only briefly refer to, in so far as it produces in some cases tanning, amounting to a perceptible relief. But that there is a further constituent is shown by the possibility of development after fixation. It appears probable that the image after fixation consists to some extent of "photo-haloid," the proportion of halide now being small. This is left behind by silver halide solvents. Oxidation agents alone remove part of the silver, leaving a second "skeleton" of photo-halide, rich now in halide, poor in silver. This is only removable by the combination of a silver-dissolving and a halide-dissolving substance, such as a mixture of sulphocyanide and nitric acid, thiosulphate and ferricyanide, or other oxidiser, or concentrated solutions of the halides.

In the more rapidly developed shadows we should expect the silver to be deposited in a less colloidal form than in the "high-lights," in consequence of which the latter exhibit the tendency to adsorption in a much more marked degree.

The existence of the photo-halides in the developed image, as of silver in the more colloidal form, would therefore be the more marked, the slower the development. This is in agreement with the formation of coloured images by restrained development with gas-light emulsions. Already nearer the soluble

condition, their fine division facilitates the process of adsorption, and we may expect the finished image to be more susceptible also to toning operations. The image in these behaves just as in plainly fixed P.O.P. The various colours are not so much to be attributed to the influence of the size of particles as to the distribution of ultra-microscopic particles in the "clumps," as experiments on the change of colour with swelling and drying suggest.

#### Adsorption-Compounds in the Completed Photographic Image.

That the image on P.O.P.—the photo-chloride—is an adsorption-compound of silver and halide follows at once from this view. It has been further suggested by Mr. Blake Smith ("B.J.," 1908, p. 141) that in the sulphur toning of bromides, silver sulphide is formed which forms a "lake" with the halide. He considers the red colour is due to an image with much chloride remaining. It may be mentioned that Pauli has shown that in the presence of gelatine—acting as "schutz-colloid"—silver sulphide is formed in the colloidal state, and that this forms adsorption-compounds both with silver and with silver chloride.

It is worth remembering that the different "modifications" of silver halides described by Stas are only modifications of the gel state, complicated by the presence of adsorbed electrolytes. Changes of colour and appearance in photographic images must not be rashly attributed to chemical alterations in the narrow sense, leading to a search for a definite reaction and a comfortable formula. The mutual protective action of the components in an adsorption-compound is shown again in the compound of chromium with silver halide formed in the process of chromium intensification due to Messrs. Piper and Carnegie. One other point about the colloidal forms of the halides and the silver + halide adsorption-compounds is their relatively greater "covering power" or opacity to light.

#### Adhesion and Surface-tension.

Having recognised that, in adsorption, the forces holding the substances together differ in some degree from those known as "chemical," it becomes of interest to consider what it is that holds the masses of substances together, whether alike or unlike. There is a common distinction made between adhesion and cohesion: adhesion for the sticking together of unlike bodies, cohesion for the force keeping the particles of like bodies together. This distinction is probably unnecessary. In both cases we are dealing with molecular forces acting only at extremely short distances. The same forces are responsible for the phenomena of capillarity and surface tension in liquids, the surface tension phenomena being obvious only at a bounding surface of a liquid, which then acts as if provided with a skin, owing to the "pull" being toward the interior of the liquid. Owing to the existence of this force, the natural tendency of a liquid is to assume a spherical surface, or generally to take a form offering the least free surface.

When a fluid is flowed over a plate, the existence of this skin becomes evident at the edges of the plate. It hardly needs emphasis that the chief function of cleaning is to remove substances such as grease, which, not "wetted" by the coating fluid, would lead to a retreat of the coating substance where they occur, and prevent the molecular contact essential to the adhesion of the film. In all coating operations it is essential to

prevent local alteration of the surface tension. Increase of temperature at a point will modify the surface tension, making the surface film weak, so that it is pulled out by the greater tractile tension of the unaffected portions of the skin. If a wet plate is sensitised, some of the ether may dissolve on the film differentially, setting up disturbances due to the difference of surface tension, which, if not equalised by careful washing, may be perpetuated as dark streaks when the plate is developed. These disturbances are well seen when camphor is placed on the water. It usually dissolves more rapidly at some points than at others, thus relatively weakening the surface of the water at that place, and so is dragged about in a capricious manner.

#### Adhesion of Solids.

In all cases of the adhesion or cohesion of substances, in order to obtain the full action of the molecular forces, they only come into play at infinitesimal distances, it is essential that the surfaces be in optical contact. Geometrically considered, they must be *enantiomorphous*—i.e., mirror images of one of the other. In considering the theory of "sticking," one must take into account the adsorbed layer of air normally present on all surfaces. One theory is that adhesives, cements, etc.—remove this, aided by pressure, and that the surfaces to be united a partial vacuum is created, atmospheric pressure keeps the joined parts together. Usually, we can distinguish three cases of adhesion.

- (1) Two soft or tender surfaces, which mould to each other.
- (2) One hard, undeformable surface, and one soft or ablen one. Realised in all photographic coatings.
- (3) Two hard, undeformable surfaces, united by a third substance, the adhesive.

In the case of photographic "coatings," the film to be coated usually acts, whilst wet or unset, as its own adhesive; in some cases, however, a substratum or cement, as in case No. 2, is employed. In all such cases it is certain that over and above the removal of any adsorbed gas or air layer there is a positive attractive action, specific in that different cases require different treatment, and it is on these lines that any true theory of adhesion must be evolved. The forces acting are undoubtedly the same as those in "adsorption." In other words, the same physical principles will have to be considered chemically as well as physically. An example may be cited of the application of colloid chemistry to the loading of paper to prevent the spreading of ink.

Paper pulp is mixed with a solution of beeswax in solution, then alum or aluminium sulphate added and starch. The various components are as follows:—The wax, in colloidal solution, and is coagulated by the electrolyte which is added. The starch acts as a "schutz-colloid," increasing the velocity of the gel formation or coagulation, and giving homogeneous action.

[The existence of elasticity or resistance to deformation of colloid media was instanced in the formation of "colloid grain," and the reticulation of dried bichromated gelatin in general (cf Ch. Gamble, Keith Lectures, 1907).]

In conclusion, it should be mentioned that the very principles of colloid chemistry are only in an embryo and unfixed. But that a unifying discipline of great value for the photographic chemist is to be found therein appears certain. It should help to lessen empiricism in this as in other branches of industrial and applied science. S. E. SHER

AN ECHO FROM THE COLONIES.—"The Australian Photo-Review," writing in its current issue, says: The "British Journal of Photography" has brought out a special "Colonial Number," so named from its contents in the way of articles and reviews of particular interest to readers abroad, and from the fact that it posts a copy of the issue to photographers and photographic dealers to an extra

number of some thousands in British possessions and foreign countries. The issue, which is that of March 27, provides a lengthy list of the many new goods on the photographic market, and its many advertisement pages show the many independent sources of supply at the service of photographers purchasing in England. A remarkable twopennyworth, and puts the 'B.J.' right up on

## BLOCKING OUT NEGATIVES.

[In the current issue of "Process Work," the always interesting monthly magazine edited by Mr. William Gamble for Penrose and Co., is a symposium on the blocking-out of negatives. The writers' opinions, quoted below, are in reply to a querist, who asked for a medium as satisfactory as, but less costly than, the "Photopake" of the Vanguard Company, but it is instructive to note that the replies, which evidently emanate from practical workers, do not confirm the querist's view as to the expense incurred by using "Photopake."—Eds. "B.J."]

Fr "F. H." finds "Photopake" a very expensive item in his business, he must do a very great amount of blocking out, as a little of this medium goes a long way and is most excellent. But I understand from the question that he requires something of a rather coarser nature, suitable for very large work. He will find the following very suitable for this purpose: Methylated spirit 4 oz., gum sandarac 1 oz. Dissolve as much of the gum as possible, leaving what is not in solution at the bottom of the bottle. For use, obtain a small wide-mouthed bottle, an empty photopake bottle will do splendidly, and half-fill it with gum solution. Then add a quantity of lamp black, sufficient to make a thick black liquid of convenient consistency. This mixture has the usual good qualities of the ready-prepared mediums, being easily applied, quick drying, and very firm and durable. Another method is to use Indian ink prepared from the tins obtainable at any artists' depot. The second quality will be amply good enough for this purpose, and come very much cheaper than using the better quality. Upon no consideration use that sold in a bottle-form, or it is likely to prove more expensive than "Photopake." Smash the ink into a fairly fine powder and dissolve as much as possible in a given quantity of water. Then to every half-ounce of solution thus made, add two to three drachms of the gum solution given above, and five or six drops of ox-gall to prevent the mixture from working greasily. So that "F. H." may have a choice of methods, I give below the way to prepare a medium for blocking out, which can be made in a very few minutes, and one that will prove effective. Obtain a 2-oz. bottle and half-fill it with pure alcohol, and add a small quantity of dye known as methylene blue, about as much as can be placed upon a sixpence, and dissolved by shaking. This medium is prepared only when wanted for use. A small piece of Avery's Backing is extracted from the tube upon a china plate and a little of the dye solution poured over it. The two are then worked together, so to speak, with a brush until the mixture is in a suitable condition for use. This medium should prove very

effective and suit the requirements of "F. H.," as a large quantity can be made at a very small cost.—ACME.

"F. H." inquires for something cheaper than "Photopake" to stop out negatives; the reply is "Mogul varnish." To use it, go round the outline with "Photopake," the large spaces can now be filled in with diluted "Mogul," using a "swan quill." To dilute "Mogul" add turpentine or benzole or a mixture of both; the dilution is complete when spread on the negative. It leaves a pale yellow deposit when looked at by transmitted light. This on the top of the negative deposit effectually prevents any light action. Diluted "Mogul" has another advantage, that if the fine lines on the negative are disregarded and covered with diluted "Mogul" they can, when dry, easily be closed or cut, using a graver or a needle stuck in a penholder, or purchase a pennyworth of gramophone needles; one obtains so many for a penny that when worn it is cheaper to throw away than regrind. New work can be inserted upon a collodion negative upon a coating of diluted "Mogul." Diluted "Mogul" is very superior to stopping out varnish, as this when diluted is of a blue-black and lets the light through, and if used sufficiently thick to obstruct light, makes it difficult to obtain sharpness if metal plates or thick paper are used to print upon.—LARKHALL.

"F. H." must have a very large quantity of negatives to block out, as "Photopake" is certainly the best, as also it goes such a long way. But a good formula is: Vegetable black ½ oz., methylated spirit 20 oz., gum sandarac 1 oz. To dissolve the gum, place it into about 2 oz. or 3 oz. of boiling water and then mix with the others; afterwards, if it is not opaque enough, add more vegetable black. This is an inexpensive formula, not only in materials, but it is a great time saver, as it dries very quickly. But I should like to suggest to "F. H." to still use "Photopake," just outline the negative with it, then cut a mask out of some red or orange paper, or even black, and paste it over the parts required to be white. This is inexpensive, and if the corners of the paper are only stuck to the negative, the same paper may be used again for smaller ones.—TRICOLOUR.

## RECENT DEVELOPMENTS IN ELECTRIC LIGHTING.

[The following article, from the current issue of "Nature," provides a review of the present position of the various types of electrical subject is of such importance to photographers fitting their premises conveniently summarised by Mr. Solomon may be recommended for careful study.—Eds. "B.J."]

An article which appeared in "Nature" last June the present writer reviewed briefly some of the improvements which had been made and promised in incandescent electric lamps. At the time that the article was written matters were in a condition of considerable uncertainty on account of the great number of new developments which had been announced, the value of which was, to a very large extent, uncertain. The frequent announcements of these improvements, which were appearing almost weekly, led electrical engineers to feel considerable hesitation in adopting any new lamp for fear that it should be superseded almost immediately after its adoption. Since that time the position has become much quieter, and during the past months the solid progress which has been made in the introduction of these lamps on the market has been remarkable. Now that considerable experience has been obtained of the working value of different types of lamp, a favourable opportunity is afforded of making a general survey of the present position and prospects for the future. At the same time, a similar survey may be taken of the conditions existing in a field of arc lighting, in which the developments during the past two or three years have been almost equally noteworthy.

### Incandescent Lamps.

As was pointed out in the article referred to above, the only two lamps which appeared to merit particular attention were the tungsten and the tantalum lamp. The tantalum lamp has now been in practical use for about two years, and has not undergone any appreciable modification since the time of its first introduction. Difficulties of producing a satisfactory lamp for use with alternating current are still not overcome, and the difficulties of drawing tantalum wire sufficiently fine to enable either low candle-power, low-voltage, or medium candle-power high-voltage lamps, to be produced still await practical solution. It is true that the range of candle-power with low-voltage lamps has been extended by the introduction of a 16-candle-power lamp, and that announcements have been made from time to time that a satisfactory solution has been found for the manufacture of high-voltage lamps. The fact remains, however, that high-voltage lamps are not yet produced commercially. The tantalum lamp has satisfactorily proved its value for electric lighting. Although the general results obtained seem to show a comparatively short average life of about 700 hours, and though the efficiency is approximately only half that of the newer tungsten lamp, it is apparent that this lamp will have

to be reckoned with for some time to come as a very important factor in the field of incandescent electric lighting. Though it may not be able to compete on the score of efficiency with the tungsten filament, yet the greater strength of the filament must always operate to counterbalance these disadvantages.

The tungsten lamp, ever since its commercial introduction into this country under the name of the "Osram" lamp by the General Electric Company, has made rapid strides in popularity. Considering that the lamp has only been on the market for a matter of about nine months its very widespread use at the present time must mark almost a record in the development of electric lighting.

In its practical performance, also, this lamp has fulfilled, or more than fulfilled, the hopes that were raised for it before its introduction. Beyond the blackening which occurs with a small percentage of these lamps, the general experience is that a life of 1,000 to 1,500 hours is obtained almost without any decrease in the initial efficiency of about  $1\frac{1}{4}$  watts per candle. This blackening appears to be a defect in manufacture, which will doubtless be soon overcome, since it is not a characteristic of all lamps, but is only observed in a very small percentage, which generally show this defect almost immediately they are put into use. The tungsten lamp has hitherto possessed the disadvantage, when compared with its tantalum rival, that it could only be used in a vertical position, but a modified type has just been introduced which can be burnt at any angle. On the other hand, the tungsten lamp has the advantage that it is suitable for use on either direct or alternating-current circuits. Up to the present the range of voltage for which the lamps can be made is practically the same as that for the tantalum lamps—viz., voltages up to 130—but the tungsten lamp has not yet been made for voltages of 100 in such low light units as the tantalum lamps, the lowest at present obtainable being approximately thirty candles. Tungsten lamps have also been made, but not yet commercially introduced, for high voltages (200 and above), and the introduction of a 40-candle-power lamp for 200 volts is promised very shortly.

It is yet too early to say precisely what will be the effect of the introduction of these two lamps on electric lighting in general. At present, for the most part probably, the lamps have been used for the lighting of factories, shop windows, and public or semi-public places where costs of lighting are very closely considered and artistic effects are of secondary importance. It is perhaps not safe to argue from the success which the lamps have attained in the past year for these purposes that they will meet with corresponding success in private house lighting, especially as in that case the size of the light unit becomes of much greater importance. It is more than probable, however, that the general public will welcome the higher light units if they provide them, as these lamps do, with a means at the same time of actually reducing their lighting bills. The present writer, for example, has substituted two 32-candle-power Osram lamps for a single 16-candle-power carbon filament lamp, and finds that it has resulted in actual saving in money, in spite of the fact that four times as much light is obtained. It is noteworthy that the fears which were expressed that the difficulties in running lamps in series would very seriously affect the introduction of metal filament lamps do not appear to have been well founded.

Beyond these two types of lamp the development in incandescent lighting has been slight. The exceedingly interesting discovery (from a scientific point of view) by the General Electric Company in America of a method for radically altering the nature of the carbon filament unfortunately came too late to have any practical effect. These so-called "metallised" filament lamps, had they come four or five years ago, would have been welcomed as a great step in advance, but, coming as they have at the same time as the metallic filaments, are practically doomed to failure, since they possess the same disadvantages, and, in addition, can only be worked at an efficiency of  $2\frac{1}{2}$  watts per candle. The same may be said of the Nernst lamp, which is almost bound to give way in the sphere of incandescent lighting to metal filament lamps. It is possible that the Nernst lamp will find a sphere of its own for intermediate lighting where light units of 100 to 200-candle-power are required, but it is much more probable that it will be ousted also from this field by the high candle-power metal filament lamps.

#### Arc Lamps.

The remarkable change in the prospect of incandescent lighting which has been effected by the introduction of the metal filament lamp has been paralleled by a similar change in arc lighting by the

introduction of flame lamps. The gain in efficiency in a metal filament lamp over a carbon filament lamp is approximately three times, an almost similar gain is obtained in a flame lamp over an ordinary open type arc lamp. The idea of introducing chemicals into the flame in order to colour the flame is an exceedingly old one, but the practical solution was not obtained until Bremer brought out his mineralised flame carbons. The carbons introduced by Bremer are mineralised carbons, in which the flame-producing material is intimately mixed with the material of the carbon rod itself. Alterations were later effected by the various carbon manufacturers, which the flame-producing material, instead of being introduced into the main body of the carbon, was only introduced into the core. The latter type of carbon is by far the most common, but carbon of the Bremer type are still in use, and have been considerably improved recently by M. Blondel, who claims to have succeeded by his employment in producing a far more efficient lamp than the ordinary flame lamp.

Flame carbons are constructed to burn with the carbons, arranged vertically above one another, as in ordinary lamps, but the general construction is to arrange the carbons side by side, inclined to one another at an angle of about 15 degrees, as shown in Fig.

The arc, which balances between the tips of the carbons, as shown in the figure, is spread out into a fan shape, and kept down at the tips by the use of a magnetic controlling field. Immediately above the arc, both in the lamps for vertical and inclined carbons, is placed an inverted cup, the object of which is to prevent the free uprush of currents of air and maintain the carbons always in an atmosphere of inert gases, thus considerably lengthening their burning hours. The cup is consequently given the name of an economiser.

The arrangement of the carbons in the inclined lamps causes a very large proportion of the light to be thrown vertically downwards, which is certainly not a desirable condition for the lighting of spaces, involving, as it does, hanging the lamps very high if illumination is to be obtained. The rich golden-yellow colour of the light, though useful for the purpose of display, is also to be reckoned as a disadvantage of these lamps. The colour is, however, very far different from that given by the incandescent lamp, and has not been found a very serious drawback. Flame arcs of other colours, for example, white and pink, can be produced, but the volume of light in these cases is greatly below that of the yellow arc. The flame arc lamp has an efficiency of approximately 0.4-0.5 watt per mean spherical candle, which is two or three times as good as that of the ordinary open type arc. The high cost of maintaining the carbons, which are expensive to make and burn rapidly, is much more than compensated by the low cost of power for a given amount of light. In the Blondel lamp the carbons which are used are of larger diameters, and are arranged vertically one above the other. This has the advantage of giving a better light distribution, and it is claimed that the mean spherical candle-power is nearly double that of the ordinary flame arc.

Whilst the flame arc has been rapidly developed in Europe, it has met with but little success in America, on account of the fact that in America the cost of labour for frequent trimming counts for more than it does in this country. For this reason the use of flame arcs in America has become almost universal, in spite of the fact that they only have about half the efficiency of the ordinary open type arc. To meet these somewhat special conditions, experimental work has been carried on during the past two or three years by M.

etz and the General Electric Company of America on the design of a long burning flame lamp. The "magnetite" arc, as called, which is the result of this work, utilises electrodes, composed chiefly of magnetic oxide of iron. In the latest electrodes, iron oxide, which produces a more intense light in the arc than iron oxide, is used, but iron oxide is still employed to give the electrodes conductivity when cold. The actual mixture contains also chromium, but this plays a purely secondary part in steady-rate at which the other oxides are evaporated.

The lamp is constructed with the magnetite electrode as the negative and a solid copper electrode as the positive. In place of copper alloy is being introduced. The arc has all the characteristics of an arc, but possesses some peculiarities due to the fact that the energy-producing material is contained only in the negative electrode. Its efficiency, from figures which have been published, appears to be in the neighbourhood of 0.8 to 1.0 watt per candle, from which it may be seen that it is a little more efficient than the ordinary arc and twice as efficient as the ordinary enclosed arc, which is its greatest competitor in America. The electrodes, when used long, are stated to have a life of 150 hours, which is as long as more than similar sized electrodes in enclosed lamps. It may therefore be seen that the magnetite arc is likely to prove a considerable advance on the enclosed arc, and where economical conditions determined the use of this lamp it is likely to be superior to the magnetite arc. It cannot, however, at present compete with the ordinary flame lamp, where the cost of trimming is not an important factor.

### Vapour Lamps.

It may be said in relation to the development of the mercury lamp. This type of lamp, which has been developed by General Hewitt in America, has not met with any extended use on account of the exceedingly unpleasant colour of the light which it gives. Though in some circumstances this may not prevent the use of this lamp, there is no doubt that it will always seriously limit its use in competition with pleasanter coloured illuminants. Efforts have been made to improve the colour by introducing other materials such as metals of the alkali group, into the tube, but these have hitherto proved unsuccessful. It is stated, however, that a marked improvement has been effected by the firm of Heraeus, Germany, by adopting quartz tubes instead of glass tubes, and the temperature at which the arc is run up to very much higher limits. By working the lamp at such a current density that the internal pressure in the tube is approximately one atmosphere, it is stated that the efficiency of the lamp is more than doubled, and a continuous spectrum is added to the line spectrum of the lamp, thus giving the light a quite pleasant and almost normal colour. These quartz-tube lamps have the additional advantage under the conditions of working the length of tube for a given light output is very much less than when glass tubes are used. The general introduction of these lamps is promised for this year. It might also be made to one other type of electric lamp as during the past year come into commercial use—namely, the tube lamp. This lamp is simply an ordinary vacuum tube of small length, and operated at a very high voltage. The tubes, of 1½ in. diameter, can be made up to 200 ft. in length, and are put up in position by welding together short lengths of tube, the energy supply being obtained by means of a transformer the terminals of which are connected to graphite electrodes at each end of the tube. The essential feature of this lamp is the method which has been adopted to overcome the difficulty that the vacuum in the tube is lost as the lamp burns, owing to the absorption of gas by the electrodes. In order to maintain the vacuum constant a most ingenious valve is employed. The main tube communicates by means of a side branch with the outer air, this branch tube being sealed by a carbon plug covered with mercury. The level of the mercury is altered by the rising or falling of a float; in one position of the float the carbon plug is completely covered, in the other it is uncovered. The movements of the float are controlled by a lever connected in series with the primary of the transformer of the tube. When the vacuum falls the conductivity of the tube increases and the primary transformer current rises; this lifts the float and causes the mercury level to fall, uncovering the carbon plug and allowing a little air to filter into the tube. The conductivity of the tube is thereby decreased, the current falls again, and the porous plug is again completely

covered with mercury. It is stated that this valve, which operates normally about once a minute, maintains the vacuum in the tube, which is in the neighbourhood of 0.1 mm. of mercury, constant within 10 per cent.

The only installation of this lamp in this country is that in the courtyard of the Savoy Hotel, and those who have seen this will probably agree that the light represents in many respects the ideal form of artificial lighting. The colour of the light given by the tube depends upon the gas which it contains, and is pure white for carbon dioxide, slightly pink for nitrogen or air. Nitrogen is stated to be twice as efficient as carbon dioxide, and slightly more efficient than air. When it is desired to operate the tube with either of these gases the open end of the valve is connected to either a phosphorus tube (to extract the oxygen from the air drawn in) or to a gas apparatus generating carbon dioxide by the action of acid on marble. The efficiency of these lamps is difficult to determine, but appears to be in the neighbourhood of 1.6 to 1.8 watts per candle.

It is interesting to note that the improvements described above in incandescent and arc lamps have once again brought electric lighting on practically the same level for cheapness as gas lighting. The introduction of the gas mantle gave gas lighting so great a superiority on the score of cheapness that for a great many years it has only been possible for electricity to hold its own on account of its many other advantages. Just as the ordinary gas mantle beat the carbon filament lamp, the high-pressure gas-mantle systems competed on an equal, or even on a slightly better, basis with arc lighting. The whole complexion which appears is now changed, since the 1 to 1.5 watt metal filament lamps can compete with the ordinary mantle for small lighting, and flame lamps are superior to the high-pressure gas lamps. It must be remembered that, from a scientific point of view, the efficiency of electric lamps is vastly superior to any type of gas lamp, the main cheapness of gas lighting being entirely due to the difference between the cost of power delivered to the lamp in the form of gas and in the form of electric energy. It is interesting to remark that, whereas the improvements in gas lighting have been effected by departing from an incandescent flame to an incandescent solid, the improvements in arc lighting have been obtained by a move in exactly the opposite direction. MAURICE SOLOMON.

### DEATH OF MR. HENRY LOMB.

CAPTAIN HENRY LOMB, one of the original partners in Bausch and Lomb, one of Rochester's foremost citizens, and a veteran of the Civil War, died on June 13, at his summer home at Pittsford, N.J., in his eightieth year.

Henry Lomb's name is, of course, associated all over the world with that of John J. Bausch, in company with whom he founded the Bausch and Lomb works. The present great works, however, started from a very small beginning, and the first days of the founders were full of difficulties, difficulties which were at last overcome by persistent courage and effort.

Henry Lomb was born in Burghaun, Hesse-Cassel, Germany, November 24, 1828. He reached America in May, 1849, and came directly to Rochester. He met Mr. Bausch and the two men started a little optician's shop, renting half a show window in the gallery of Reynold's Arcade. Captain Lomb had saved \$60. He lent his friend this sum and it was put into the business, the small beginning of the great industry. It was agreed that as soon as the business warranted Mr. Lomb should join the firm as a half-partner. It was in 1855 that Captain Lomb's active association with the firm began. At first Mr. Lomb attended to the business in Rochester, while Mr. Bausch visited the neighbouring towns. A little later Mr. Lomb learned to fit eyes, and he, too, took to the road.

Little by little the business of the firm increased, but it was still struggling hard when the Civil War broke out. It was a severe sacrifice for the young partner to leave the business, which was just getting on its feet. But here, as elsewhere, Captain Lomb never hesitated when it was a question of duty. On April 23, 1861, he enlisted in Company C, 13th Regiment, New York State Volunteers. He was elected first sergeant, promoted to first lieutenant, and in 1862 was promoted to be captain of the company. With his company Captain Lomb participated in many of the fiercest battles of the Civil War, and time after time showed distinguished bravery.

Probably no man in all Rochester will be more universally regretted,

or has, in the quiet, unostentatious way which was characteristic, done more for Rochester, its institutions, and its people than Henry Lomb. Captain Lomb, as he was affectionately known, was a man of the most quiet, retiring disposition, but no man was more of a philanthropist or more willing to aid distress.

## Exhibitions.

### THE INTERNATIONAL EXHIBITION IN THE NEWCASTLE ART GALLERY.

A collection of pictorial photographs, representing the work of the most distinguished pictorial photographers of the world, was recently opened in the Laing Art Gallery, Newcastle-upon-Tyne, under the auspices of The Laing (Municipal) Art Gallery Committee of the Corporation of Newcastle-upon-Tyne.

This collection is one of a series of special exhibitions illustrative of the various schools of British and foreign painting, etchings, engravings, etc., and it is an interesting feature that the committee of the Laing Art Gallery have thus recognised the important educational value of pictorial photography. Of course, in an exhibition of this character, which was international, and by invitation only, it was necessary that the compilation of a suitable list of exhibitors, to be invited to contribute work, should be undertaken with the greatest possible care, and in this work the Curator of the Laing Art Gallery was assisted by a small committee, Messrs. David Blount, Walter S. Corder, and Arthur Payne, who were asked by the Northumberland and Durham Federation of Amateur Photographers to undertake this work. The exhibitors were given a free hand as to the pictures they selected to be hung, and in some instances it is very interesting to note that they have not sent their most popular work.

The following is a list of the exhibitors with the number of their exhibits:—

British School.—J. Craig-Annan, 7; Mrs. Barton, 8; W. Benington, 3; David Blount, 8; Reginald Craigie, 1; W. Crooke, 10; F. H. Evans, 6; C. F. Grindrod, 6; A. Horsley Hinton (the late), 4; F. Hollyer, 5; Charles Job, 6; A. Keighley, 6; Percy Lewis, 4; Right Hon. Viscount Maitland, 2; F. J. Mortimer, 4; J. C. S. Mummery, 6; J. Cruwys Richards, 3; W. A. Stewart, 6; J. C. Warburg, 6; H. Vivian Yeo, 7.

American School.—C. Yarnall Abbott, 5; John Beeby, 6; Alvin Langdon Coburn, 10; F. H. Day, 1; Gertrude Käsebier, 7; Mrs. Eva Schütze, 7; Miss K. S. Stanbury, 5; Mrs. Mary Stanbury (the late), 3; Edward J. Steichen, 10; Alfred Steiglitz, 10; Miss Mathilde Weil, 6; Clarence H. White, 10; Baron A. de Meyer, 10.

French School.—René Le Bégue, 5; Maurice Bucquet, 6; Robert Demachy, 6; C. Puyo, 4; René Michan, 3; Vicomte P. de Singhy, 2. German School.—Rudolf Dührkoop, 12; Albert Gottheil, 6; T. and O. Hofmeister, 12; Ernst Müller, 6; Otto Scharf, 6.

Austrian and Hungarian School.—Dezső Feledi, 5; Heinrich Kühn, 7.

Swiss School.—Fred Boissonnas, 3.

Italian School.—Dr. E. G. Boon, 6; Guido Rey, 2.

Belgian School.—Charles Gaspar, 6.

The total number of pictures is 330, and they are hung upon the walls and on screens in Galleries A and B. The American section has the dignity of a room to itself, and these pictures are delightfully arranged upon the walls, that have been covered with a soft grey coloured sacking, by Mr. Alvin Langdon Coburn, who travelled down to Newcastle on purpose to do this work. The remainder of the exhibits are hung upon walls that are of an ugly reddish plum colour, and principally on this account do not look so attractive as the American section. It would have been an improvement if these walls had been covered with brown paper before the pictures were hung.

The exhibition has attracted considerable attention, both from the local artists and art critics, as well as from the photographers, and it is very interesting to note the opinions of those visitors. Some of the photographers admit that they do not understand much of the work that is shown, it is so very different from what they have been accustomed to expect in a photograph. Others go into raptures over the more eccentric pictures, and talk learnedly of tone values, texture, composition, feeling, etc., until one begins to wonder how many of them are "poseurs."

The opinions of persons who are outside photography but interested in art will appeal most to the readers of a photographic journal. Therefore we may at once say that a local artist of repute, a person referred to the work shown at this exhibition in an unreservedly contemptuous manner. And in direct opposition to this we have an opinion from another artist, Mr. Slater, who is a frequent exhibitor at the Royal Academy, and who is delighted with the high character of the work, and would not hesitate to hang many pictures on his walls to admire as works of art. He thinks the British school is far in advance of the others, though he has many pictures to admire in the other sections, and especially the German and American schools. Another art critic, a lady, is tremendously impressed with the power possessed by the photographer for rendering artistic impressions, whilst we also have Americans admired for the extraordinary success with which they selected a commonplace subject, and so treated it as to produce a beautiful decoration.

Mr. George Hughes, a picture dealer and art critic of reputation in the Tyne, writes us as follows of his impression of the exhibition:—

"The scope of photography would seem to me to lie in its means of expression of what the photographer deems beautiful picturesque, and this discrimination constitutes the artistic value which is the primary value, the mode of expression (in the case the camera) being relative. A walk round the exhibition suggests that the main object of many exhibitors appears to be muzzing up a print into as close a semblance as possible of an oil or a mezzotint after a picture by a painter, and herein their weakness lies, as a confession of weakness. The prints may be like an oil or mezzotint, but this is at once to relegate photography to much lower standard than ardent photographers would have it. Photography, I would think, should only be a means of expression of the feeling of its user, and not (however capably done) a means of indifferently imitating work in another medium."

It is only fair to mention that several of the photographers who were invited to contribute work could not do so, for various reasons, probably the most serious omissions being Mr. George Davis and Mr. Malcolm Arbuthnot.

The exhibition will remain open for several weeks, and is open on Monday, Tuesday, Wednesday, and Thursday, from 10 a.m. to 7 p.m.; Friday, 2 p.m. to 6 p.m.; Saturday, 10 a.m. to 6 p.m.; Sunday, 3 p.m. to 5 p.m. Admission free.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between June 27 and 27:—

DRY MOUNTING.—No. 13,255. Process for mounting photographic engravings, or the like, in a dry condition. Julius Neuberg, 65, Chancery Lane, London.

WASHING NEGATIVES.—No. 13,281. Negative washing holder. Henry Rubenking, Junr., 27, Chancery Lane, London.

LEVELS.—No. 13,536. Improvements in optical level indicators, cameras and the like. Charles Percival Truscott, 88, Chancery Lane, London.

GLAZING.—No. 13,592. New or improved process for gelatinizing glazing paper, cardboard, and the like. Armitage and Hill Limited, and Richard Franklin Woodburn, Tower Works, Halifax.

CINEMATOGRAPHS.—No. 13,663. Contrivance to be attached to a cinematograph for the purpose of extinguishing fire in the case of the celluloid films used in conjunction with a cinematograph becoming ignited. Thomas Barrasford and William Faulkner, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, W.C.

SELF-DEVELOPING PAPERS.—No. 13,835, 1907. Bromide or other photographic paper, printing-out paper, and similar sensitive surfaces.

dered self-developing or capable of being developed (by the application of water only), and at the same time are made non-soluble. The back or unsensitised surface of the paper is supplied with a layer of the concentrated developing mixture containing borax, as a preservative and alkaline constituent, or a soluble salt or boric acid may be used as a preservative, either in an aqueous mixture or in conjunction with some other substance as an additive.

The mixture, which for effective, economical, and commercial reasons, has been found to give good results for ordinary bromide gaslight papers is:—

Metal .....	2 grains.
Hydroquinone .....	5 grains.
Potass. metabisulphite (or soluble acid sulphite) .....	$\frac{1}{2}$ —1 grain.
Potass. bromide .....	$\frac{1}{2}$ grain.
Borax .....	10—20 grains.
Gum or other suitable colloid .....	$\frac{1}{2}$ grain.
Water .....	sufficient to make a thin paste.

The above is suitable for from a quarter-plate to a half-plate size. It will be well understood that the developer must be compounded in varying conditions and various papers or surfaces, and the use of metal and hydroquinone, amidol, eikonogen, or other substances may be used.

The materials, having been ground together and well mixed, may be applied by means of a brush or other convenient device to the back of the sensitised paper, which is then allowed to dry.

When the dry developing composition is used in conjunction with printing-out paper which has only received a fraction of the full exposure, and it is wished to complete the photographic development, the borax of the above formula may be used wholly or in part by boric acid and the proportion of sulphite increased, or the preparation rendered acid by other substances.

Under certain atmospheric conditions, it may be expedient to use as a protective medium for the developer a coating or wash of an arabic or saccharine substance, such as ordinary sugar, in solution, or a mixture of both. The saccharine substance may, however, be used in conjunction with the gum, or other suitable material, in compounding the mixture. A further advantage arising from the use of sugar is that protection is afforded against oxidation and it also has a hardening and stiffening effect. The developer may be applied as a single coating or layer occupying the whole or a portion of the back of the support, or the developer may be applied in bi-part, tri-part, or any other desired manner, the acid and reducing constituents being mixed and applied separately on one part of the back of the sensitive material; the developer or any other alkaline substance can be applied to another portion of the surface, and the restraining potassium bromide may be applied to a third area or part, but otherwise the bromide may be associated with either part of the bi-part division. Another bi-part division that may be used is boric acid, bi-sulphite, and bromide as the reducing agent, and for the other part an alkaline salt such as carbonate of soda. If desired a pigment or colouring matter may be applied between the back surface of the support and the developer, or a separating or protective medium of an impervious nature may be interposed. This medium may be a layer of a resinous material which will soften by heat, and as the resinous material will remain after development it may form a necessary support for dry mounting or for mounting by heat and pressure. An instance of a resinous material suitable for employment, such as shellac or the like may be mentioned. It is often desirable that the adhesive and separating stratum should be soluble, in which case the adhesive stratum may consist of a piece of paper or the like thoroughly saturated with the resinous material, or it may be a thin sheet of gutta-percha, balata, or the like. This procedure has the advantage of allowing the separating stratum with its coating of developer to be stripped off when required, as, for example, in the case of a printing-out paper which has received the full exposure, or when some special treatment is desired. The separate sheet or strip, consisting of a piece of film coated on one side with the dry developer, can be used on any suitable sensitive paper.

Reference is made by the patentee to specification No. 8,911, 1905, nothing in which is claimed in the above. William Fraser Claughton Kelly, St. Albans, Upland Road, Leigh-on-Sea, Essex.

The following complete specification, etc., is open to public inspection before acceptance under the Patents Act, 1901:—  
PHOTOGRAPHING LANDSCAPES.—No. 13,128. Method of and means for taking photographs of landscapes. Neubronner.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Hypo-Alum Toning of P.O.P.

The bath I use (says Mr. H. Jeffreys in "Photography and Focus" for July 7) has the formula: Hypo 3 ounces, alum  $\frac{1}{2}$  ounce, water 1 pint. This contains a large excess of hypo, and can, therefore, be used as a combined toning and fixing bath. Printing is carried to about the same or to slightly less depth than usual, and the print is placed in the bath either with or without previous washing. It immediately turns orange-brown, similar to the colour of prints merely fixed without toning. The tone then gradually changes to an excellent brown, apparently permanent, but I have not had sufficient time to test.

As the colour cools it becomes a purple, which is not altogether satisfactory, then black, and then slowly fades to a yellowish colour. If left in much longer it turns to white paper. There appears to be a quantity of alum unacted upon in the bath, as it also has a hardening effect, so that prints toned in this bath can be glazed without further treatment.

Thus its advantages over gold toning seem to be that:—

- (1) There is no change in tone after removal from the toning bath.
- (2) A bath containing only two ingredients and costing practically nothing, serves the threefold purpose of fixing, toning, and hardening.
- (3) It is extremely simple in use.
- (4) Toning is perfectly even.

Its disadvantages are:—

- (1) Only one tone is really good, which is the brown. The purple-brown is also good, but beyond that the tones are poor.
- (2) It is slow in action, although not excessively so, the brown being obtained in about ten minutes. However, this is more than compensated by the fact that only one bath is needed.

## New Books.

"Le Procédé Ozobrome." By E. Coustet. Paris: Office of "Photo Revue." 60c.

M. Coustet, in his historical and theoretical introduction, cites a number of processes which really are irrelevant to his subject proper, and his only conclusion from them is that ozobrome is a most misnamed process, having nothing to do with ozone or bromine. However, these considerations do not delay him long from dealing with the practical working of the process. This portion of the volume gives useful instructions in the making of carbon prints and enlargements by Mr. Manly's most valuable process, and it adds some chapters on other applications of ozobrome, such as lantern-slides, intensification, gum-ozobrome, collotype, and oil. Apparently the manual was in the press at the time of Mr. Manly's recent introduction of the acid bath method, of which no mention is made.

"One Thousand Ways and Schemes to Attract Trade." By Irving P. Fox and B. A. Forbes. Boston, U.S.A.: Spatula Publishing Company. 4s.

The authors of this volume are connected with two technical publications—one, "The Spatula," dealing with the drug trade.

Their compilation consists of a collection of numerous ideas, "business pointers," drawings, and typographic displays, which can be used by a retail dealer to attract trade. Though many of these recommendations apply specifically to the retail chemical trade, many other shopkeepers might take advantage of them, and would often find occasions when the original devices for calling attention to an article would prove of service and profit. Apparently the American advertiser has no scruples as to the methods which he may adopt in thus obtaining publicity to an article of commerce. Thus our authors mention, among others, in one place the instance of a soap advertiser who booked a whole front row of stalls at a theatre and sent to fill them twenty bald-headed men, each with the words "So-and-So's soap" painted on his scalp. London is named as the scene of this bright gem of the advertiser's art, though we should like to have chapter and verse for the incident. This, however, is not to say that many of the recommendations are of a similar sensational character. Most of them are not, and a professional photographer or photographic dealer might do worse than turn over the leaves of the book in a spare hour. The publishers intimate that British stamps are accepted in payment.

"Kunstliche Gebirgsphotographie." By Dr. A. Mazel. Translated by Drs. E. Hegg and C. Stürenberg. Second edition. Berlin: Gustav Schmidt. M4.50.

Mountain photography has a great attraction for the Germans, as witness the popularity of a little book on the subject by Herr E. Terschak and the issue of the present second edition of Dr. Mazel's larger work, while one may also see evidences of the same love of the stupendous in scenery in the numbers of cameras taken every year to the Tyrol by German tourists. It is not surprising, therefore, that a lengthy treatise such as the present one should obtain a greater circle of readers in Germany than in the country of its author. Dr. Mazel, as a past president of the Geneva Photographic Society and member of the Swiss Alpine Club, may claim to bring both photographic and mountaineering experience to his subject. It is evident, too, that the æsthetic aspect of Alpine and other mountain photography is one which strongly appeals to him, and one in which he is desirous of instructing others. The selection of apparatus, plates, iso screens, and other essentials is the theme of his earlier chapters, and it is interesting to find him most emphatic in directing the use of orthochromatic plates. His particular preferences in this direction are of less interest to the English reader, since he selects only from Continental makes. The major portion of the volume, however, is taken up with chapters on the essential features of Alpine and other mountain landscapes, in the course of which the author gives several diagrammatic sketches of the composition to which one subject or another lends itself. If this advice savours of the dogmatic, it should, nevertheless, help the beginner in mountain photography to avoid the confused assemblages of pines, rocks, and mountain tops which make up so many of the photographs hurriedly taken in the Alps. The exceptional opportunities of early morning and late evening, both in summer and winter, are emphasised by Dr. Mazel, who in a later portion of his book advises on the planning of a mountain tour. A number of half-tone plate illustrations from the author's negatives give point to the many practical suggestions, and are a fitting appendix to a most excellent volume.

"THE TELEPHOTO QUARTERLY."—No. 2 of Captain Owen Wheeler's quarterly, "T. Q.," comes to us pleased at the good reception—quite deserved—of its first issue. In the current number Mr. Clifton has some useful notes on the telephoto lens in natural history, and the editor's article on instantaneous telephotographic work with the hand camera contains some timely advice from the writer's practical experience. "T. Q.," as an organ of its special branch of work, is evidently living up to one's expectations of it.

"LEITFADEN DER LANDSCHAFTSPHOTOGRAPHIE."—The third edition of this work on pictorial landscape photography reaches us from the press of Herr Gustav Schmidt, Berlin. The author, Herr Loescher, may be congratulated on the practical approbation conferred upon his work by the call for three successive editions within the space of a year or two. And equally his readers may be commended for taking to heart the teachings of a worker who puts good photography in the place of honour and abstains from glorifying the spurious products of one "faking" method or another as "art in photography." Herr Loescher's volume is among the soundest and sanest text-books of outdoor photography,

and text and illustrations (both by the author) propound a sane practice.

"THE PHOTOGRAPHIC ANNUAL."—Since reviewing Mr. Dawbarn and Ward's new reference volume last week we received the "cloth" edition, which, in addition to being strongly bound, is interleaved with thin blank pages, on which additional "figures, facts, and formulæ" can be written. The price of the cloth edition is 2s. net.

## New Apparatus, &c.

The Welborne Piper Photographic Clock (New Model). Sold by Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

In the new pattern of this piece of apparatus a number of improvements have been made which further fit the clock for all the purposes of timing photographic operations, in addition to permitting its use for ordinary domestic purposes. The range of movements of the clock is a wide one, so wide, in fact, that some little study

various keys is necessary before a specific use can be made of the clock. However, an hour spent in following out the instructions given by the makers will render the worker familiar with the movements, and the clock will be found to be extremely convenient for use for a large variety of photographic purposes. In preparing to detail the various ways in which the clock may be set, we will briefly explain the function of the adjustments shown in the diagram by the letter A to K.

A, lever which causes the gong to ring every minute (M), or every hour (H, on right).

B, lever controlling the striking of the gong each minute (M). If pressed back, gong does not sound, and clock acts as silent piece. Pull forward to allow gong to sound.

C, lever putting alarm-signal out of action.

D, lever transforming rings of the gong into clicks.

E, lever which, when raised, stops the clock when the hand comes to zero.

starts clock which has been stopped at zero by pushing up E.  
stop lever arresting clock either permanently or as long as it is  
down, according to position of  
which is set to T (time) or B (bulb), according as clock is  
ed to be stopped by pressing down lever G and releasing it,  
pping down lever G.

brass nozzle for starting and stopping clock by pneumatic  
re.

lunger for working shutter at same time as clock.

facilities given by the clock can best be summarised by saying  
the clock will time both short and long periods either by  
tion of the seconds', minutes', or hours' dial, or can be  
ed to indicate the end of any pre-arranged period by a gong.  
various uses to which it can be put in this way may be best  
ed by quoting from the portion of the instruction dealing  
ne photographic uses of the clock.

ing Quick Development in Light.—Use the time-setting and  
atic stop, timing from zero, and start clock by pressing the  
the developer is poured on. When the last full minute has  
l, reset the automatic stop, and the clock will again stop at  
ady for the next operation.

ng Quick Development in Darkness.—If developing for an  
short number of minutes, set the clock just as described, and  
y the bell alone. If parts of a minute are to be included,  
e clock at the right number of seconds before zero so that the  
development may be denoted by the sound of the bell.

ng Slow Development.—If development occupies more than  
ten minutes, it is convenient and quite sufficiently exact to  
y the approximate method.

loping by the Watkins System.—Use time-setting and auto-  
top, starting clock from zero as developer is poured on. The  
t the image first appears press the ball and so stop the clock.  
ff the time, and then relax ball and restart clock. The time  
arance multiplied by the Watkins factor for the developer  
ll give the total time of development required. By using the  
e way described, the time of appearance can be determined  
curately, and the stoppage of the clock for a second or so  
ne time is being read is of no consequence.

oping Slides and Prints.—If many prints are required from  
ative, uniform results can be easily secured even with a very  
veloper, as it is easy to time to a second with the aid of the  
Using the automatic stop and time-setting and treating one  
t a time, it is easy to develop at the rate of one print per  
with a developer that completes its work in about half a

ng Exposures with a Shutter.—Set the clock to "time" or  
according as the shutter is set, and stop the clock with the  
hand in a convenient position. If the balls are pressed  
eously, the clock and shutter work exactly together, and  
e can be timed to a nicety. With the aid of a Y junction  
es of clock and shutter can be linked together, so that both  
ated with one ball, but it is generally sufficient to press the  
ts together in one hand. The co-operation of shutter and  
of great value in the following cases:—

When the subject is liable to move, use time-setting, and on  
st sign of movement press ball and so close shutter and stop  
The exact time can then be read, and you can judge whether  
posure be sufficient. Pressure on the ball must be sustained  
the time is read.

When enlarging and it is necessary to screen or "dodge" the  
ement, use time-setting and proceed exactly as when develop-  
darkness. You can then devote your attention to screening  
largement without looking at the clock at all.

When owing to vibration of traffic, etc., intermittent expo-  
sures to be given, if a shutter of the "automatic" or "ever-  
rarity is used, and the clock and shutter are both set to  
you can by pressing the ball simultaneously open shutter  
rt clock, and by relaxing the ball close shutter and stop any  
e of times during the exposure, and the total time of expo-  
ill be accurately recorded by the clock regardless of the  
e of stoppages. This is a most valuable application of the  
especially in photo-micrographic work, and if the shutter  
ed in front of the source of light, it can be used without  
ur of vibration due to its action.

When making a number of lantern slides from one negative

by reduction in the camera, with ball-setting and automatic shutter  
a series of exactly equal exposures can be given as rapidly as the  
plates can be changed. This saves much time, and ensures uniform  
results.

Toning and Similar Operations.—When it is desired to put a  
number of prints through some solution for a certain definite number  
of minutes, use a dish that will hold as many prints as there are  
minutes in the time of the operation, and number the prints in  
pencil on the back. Then, commencing with No. 1 print and working  
upwards, put one print in the dish every time the bell rings until the  
first print has been acted upon sufficiently. After that take out  
the lowest numbered print in the dish and put in a fresh one every  
time the bell rings. If a larger dish is used and the prints are  
inserted and taken out in batches of two or three, a much greater  
number can be dealt with in the same time. By working in this  
manner uniform results can be readily ensured.

Timing Washing, etc.—Set the alarm so that it will sound at the  
proper time. By its use you can avoid over or under washing, and  
also waste of water. For short operations taking less than an hour  
the minute alarm is, of course, used.

Automatic Time Exposure.—Set clock and link to shutter as  
described. Set shutter to time and open shutter by hand and start  
clock simultaneously. When clock strikes, or alarm sounds, the  
shutter will close and the clock will stop at the same moment.

Automatic Instantaneous Exposure.—Set clock and link to shutter  
described. Set shutter to time and open shutter by hand and start  
and when clock strikes the exposure will be made, the clock stopping  
and recording the exact moment.

The clock is strongly made, and is evidently able to withstand a  
good deal of ordinary wear and tear. Its price is 42s., complete  
with long length of tubing and pneumatic ball.

## CATALOGUES AND TRADE NOTICES.

BUTTON PHOTOGRAPHS.—A new price list of apparatus and materials  
for the production of button photographs has been issued by the firm  
of Fallowfield, which for years past has kept its clients supplied with  
the latest patterns of goods of this class. Mr. Fallowfield supplies  
cameras, button parts, button machines, and the various forms of  
jewellery in which the button photograph may be finally mounted.  
The list, which is obtainable free on application to 146, Charing Cross  
Road, W.C., is certainly indispensable to those going in for this  
branch of work.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, JULY 11.

Chelsea and District Photographic Society. Excursion to Windsor.  
Aberdeen Photo Art Club. Excursion to Loch of Park.  
Handsworth Photographic Society. Excursion to Bridgnorth.  
Manchester Amateur Photographic Society. Excursion to Grindelford.  
South London Photographic Society. Excursion to Chorley Wood.

#### MONDAY, JULY 13.

Southampton Camera Club. "Ozobroma." H. W. Miles.

#### TUESDAY, JULY 14.

Royal Photographic Society. Ordinary Meeting for the Election of Members.

#### WEDNESDAY, JULY 15.

North Middlesex Photographic Society. "Home Portraiture." A. H. Lisett.  
Denham Outing Print Competition.  
Rugby Photographic Society. Excursion to Brandon and Wolston. F. Betts.  
South Suburban Photographic Society. Portfolio and Print Competition.  
Balham Camera Club. Discussion: "Faulty Negatives."  
Southampton Camera Club. Excursion to Brockenhurst. C. M. Cooper.  
Leeds Camera Club. "Home Made Apparatus." W. W. Manfield.

ROYAL PHOTOGRAPHIC SOCIETY.—The attention of members may  
be drawn to the meeting for Tuesday next, July 14, at which persons  
who have applied for membership since the last ordinary meeting  
will be elected. In previous years this meeting has usually been  
provided by the secretary with some topic for discussion, or has  
had exhibited to it some photographic novelty.

## News and Notes.

MR. AND MRS. SNOWDEN WARD, we hear, are to visit America in the coming winter, where Mr. Ward will deliver a series of lectures, illustrated with photographic lantern slides from Mrs. Ward's negatives. The subjects are to include "Shakespeare at Home," the "Dickens Land," "Chaucer and the Pilgrim's Way," and the "Land of Lorna Doone."

ACCIDENT TO THE REGENT STREET KODAK DEPOT.—Last week a motor 'bus plying between Brixton and Hammersmith plunged on to the pavement when half-way down Regent Street, and crashed into the premises of Kodak, Ltd., bringing down the brickwork of the lower part of the column which forms the left door-post. The accident was due to the omnibus getting in difficulties with a motor brougham, which collided with it in such a way as to affect the steering gear.

PROFESSIONAL REQUISITES.—Messrs. Sichel and Co. advise us that they have just collected the contents of a West End studio, including two studio cameras with suitable lenses, "Sickle" background, stand with four rollers, three backgrounds, accessories, Cooper-Hewitt mercury-vapour portrait apparatus, all of which they have on show at 52, Bunhill Row, and are prepared to dispose of at greatly reduced prices.

THE ANNUAL SOIREE of the Royal Society of Arts was held this year in the Natural History Museum on July 2, when a large number of members and their friends were received by the president, Sir Steuart Colvin Bayley, and spent a pleasant evening in the spacious galleries of the museum. Several programmes of vocal and instrumental music were performed and the function, though perhaps lacking the charm of surroundings of the Botanic Gardens, where the soiree has been held in the past, provided most enjoyable opportunities for the meeting of many persons interested in the industrial and other subjects which the society has made its special care.

AN AUSTRALIAN NATURE-PHOTOGRAPHER, who would appear to have been working contemporaneously with the Kearntons, R. B. Lodge, and Oliver Pike in this country, is the subject of a long and interesting illustrated interview in the current number of our Melbourne contemporary, "The Australian Photographic Journal." Mr. Sidney W. Jackson has seen life in many strange places, far from the haunts of civilisation, but his photographic labours have been bent in the direction of recording the habits of the birds and beasts of the Antipodes almost as thoroughly as has been done in these islands by enthusiastic British workers. His work obtains an extremely good showing in our Melbourne contemporary, the "production" of which is equal to that of any English photographic journal.

## Correspondence.

- \**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \**We do not undertake responsibility for the opinions expressed by our correspondents.*

### SCULPTURE AND PHOTOGRAPHY.

To the Editors.

Gentlemen,—The "Magpie" of the "A.P. and P.N.," whoever he may be, says that the art specialist of the "B.J.," who, as most people know, is myself, rushes in and recklessly charges Mr. Bertram Park with passing off the photograph of a statue for one taken from life. That certainly was the charge; but it was made neither in a rush nor recklessly. It is upheld now, and will remain so.

Mr. Park, the plagiarist, also writes to tell your readers that I absolutely identify his picture with a statue by "the late Onslow Forbes," which, he admits and regrets, he had never heard of till now. Neither had I till now. The name I mentioned was Onslow Ford. Perhaps that is a small detail to the "A.P. and P.N.," which, in its earlier and simpler form, had a reputation to lose for art culture. But why does Mr. Park write to tell your readers that

I identify his photograph with the statue? Of course I do. Surely that fact is a week old. He is telling them an appalling untruth when he says that I state that, by the "control" of the pigmenting brush one can photograph a statue. I take this opportunity of informing your readers that really I am not a lunatic, in spite of Mr. Park's implications.

Of course, consciences are not equally elastic; but most promoters of exhibitions would have withdrawn so barefaced a plagiarism as Mr. Park's immediately upon the fact being pointed out. Moreover, neither Mr. Park nor the "Magpie" are bettering their case by stooping to journalistic trickery for the purpose of throwing dust in the eyes of the public. I am sending a copy of this letter to the "A.P. and P.N."—Yours truly,  
F. C. TILNEY.  
4, St. Oswald's Studios, S.W.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with fee.*

### PHOTOGRAPHS REGISTERED:—

E. C. Cooper, 49, Spring Bank, Hull. *Two Photographs: Groups of the Wesleyan Methodist Local Preachers' Mutual Aid Association Meetings at Hull.*  
S. A. Driver, Riddlesdale House, Ardlough, near Colchester, Essex. *Photograph: Dedham Mill, Essex, on Fire.*  
T. J. Hanstock, 3, Pilgrim Street, York. *Photograph of Mrs. Dudley-Smith and her Horse.*

TONING BROMIDES.—Would you kindly instruct me how to tone formulae given in the "Almanac" of 1907 (page 798) by J. Sedlacek for bromide toning (brown to violet-black)? I have treated Kodak, also Rotograph papers, using chemicals and exact quantities given, mixed in reading order, both in hot and cold water, but failed to get tone required (violet-black). Prints bleach quickly, but do not seem to move in toning bath after reaching a muddy yellow or light sepia, or with soda carbonate or water black. Prints are well washed before and after bleaching.  
PRINTER.

We gave the formulae as they appeared in the German, although we have not tried these particular prescriptions we have used some very similar ones for lantern slides, on which a considerable range of colours is obtainable by the use of hypo, sulphur metabisulphite. We should think the darkening solutions are strong enough in your case, as the tone apparently does not get to the last stage. Try solutions five times the strength. You might also add a little hydrochloric acid, say five drops per ounce to the mercury and bromide solution.

DISHES AND FIXING.—(1) Will dishes, etc., made of lead be detrimental to use for rodinal, metol, hydroquinone, and hypo solutions? (2) In (hypo 1 lb., water 100 oz., liquid bisulphite 1½ oz., or alum ½ oz.) how many 20 x 16 enlargements can I make? Also, any means of telling when fixing solution is no use for small prints? (3) Is liquid bisulphite and alum added to fixing beneficial or not? (4) Is a metol hydroquinone developer suitable for stand development? If so, how much must I dilute my pre-developer? In one part of developer how much water, also duration of time for development?—W. T. H.

(1) They are suitable. (2) We can give you no safe rule, except that you test the bath with a spare unfixing plate, noting the time taken to clear the plate by removal of the silver bromide. If it becomes unduly long you may depend the bath is becoming exhausted. It is a mistake to economise in hypo. (3) Certainly, I

hardening action on the gelatine surface, which is sometimes necessary (with some papers and in warm weather), especially when prints are to be sulphide-toned. (4) Certainly about five or ten times—i.e., 1 oz. of present formula to 1 oz. of water. You can only find a time of development by trial with the test plates. (5) We can only refer you to our advertisement pages.

**PENANCE.**—We have made inquiries, but cannot trace a maker of photo-stains named Whittaker. You can purchase several kinds of photo-stains and dyes from the large dealers.

**ALMANAC.**—The ferricyanide bromide formula, given in the "Almanac," page 825, is as suitable as any. A quicker process is to bleach the prints with weak bromine water, but the drawback is the irritating vapour which escapes from the bath. If we can advise you what respect the colour of your prints is unsatisfactory we will advise, but "rotten" does not tell us much.

**RIGHT TO COPY.**—Some weeks ago a firm of photographers in London took a photograph of a large regimental dinner party at one of the large hotels. Copies were ordered and paid for by those diners that required them. My son was one of the party and brought a copy. He and some of his friends wish to have some copies of the photograph, and have asked me to do some for them. Can I do this for them? Seeing all copies supplied by the photographer were paid for, is the copyright vested in them? I have written to the photographers asking permission (on a stamped addressed envelope), but they have not replied.

**DOUBTFUL IF THE PHOTOGRAPHER WAS PAID FOR TAKING THE GROUP.**—It is doubtful if the photographer was paid for taking the group. It is not his responsibility for paying him can allow you to copy it, as it is theirs, but it is conceivable that the photographer would do the job "on spec.," in which case the copyright would be his even though he sold copies. We should advise you to learn the facts of the case before doing anything.

**SUCH PRINTS GIVE SOFTER OZOBROME COPIES, BUT IT IS EASY TO MAKE THEM BY USING A WEAKER PIGMENTARY SOLUTION FOR RATHER LONGER TIME OR ADDING A LITTLE AMMONIA TO THE BATH.** You will find some information on this subject in the "Almanac." Certainly, the two are bona-fide.

**BROMIDES.**—1. A bromide enlargement, rather dark, was made with ferricyanide of potash, but will not darken with sulphide. The developer used is not now known. Can you advise anything likely to darken it? A border cut off does not help. 2. Can you give me proportions of hypo and alum for developing bromides? None of the makers appear to know.—A. O.

**A SOLUTION OF SCHLIPPE'S SALT, 10 GRAINS TO THE OUNCE. WE CAN ONLY HEAR OF THIS DIFFICULTY, BUT, EXCEPT FOR A STALE SULPHIDE SOLUTION, WE KNOW OF NO SATISFACTORY EXPLANATION OF IT.** 2. Hypo, 1 lb. to 200 oz.; dissolve and add alum, 1/2 oz. Filter. The prints are better as it becomes older.

**PRINTS.**—I should feel much obliged if you would kindly let me know in next week's "B.J." whether you know of makers of prints which would trim prints (with same size tissue fixed back) at right angles when placed one on another, say five or six. If so, it would save a deal of labour in trimming and would turn out the prints perfectly square and ready for mounting.—J. T.

**HOW OF NO SUCH MACHINE BEING ON THE MARKET. PROBABLY THE DRY-MOUNTING COMPANY, FETTER LANE, E.C., CAN BE ABLE TO HELP YOU. A MACHINE SUCH AS IS USED BY THE DRY-MOUNTING COMPANY FOR TRIMMING THE LEAVES OF BOOKS AFTER THEY ARE TOGETHER WOULD NO DOUBT ANSWER YOUR PURPOSE QUITE WELL, BUT SUCH MACHINES ARE SOMEWHAT COSTLY.**

**MR.—I HAVE READ THAT PAPER IS NOW MADE AS SENSITIVE TO LIGHT AS THE MOST RAPID PLATE. COULD YOU INFORM ME WHERE I MIGHT OBTAIN A QUANTITY OF SUCH PAPER? I WOULD REQUIRE IT IN QUANTITY FOR SPECIAL EXPERIMENTAL PURPOSES.**—E. J.

**WE HAVE BEEN MISINFORMED. THE MOST RAPID PAPERS ARE THOSE OF THE "ULTRA" CLASS, BUT NONE ARE AS RAPID AS THE VARIOUS ULTRA-SENSITIVE PAPERS.**

**MR.—WE HAVE NOT HEARD OF THE PROCESS, BUT WE SHOULD BE INTERESTED TO HEAR OF THE VALUE PLACED ON IT BY THE VENDOR. USUALLY SUCH METHODS ARE NOT WORTH WHAT IS ASKED FOR THEM.**

**ANXIOUS.**—The method is to place a thin piece of celluloid film between the negative and the bromide paper when printing. The cards are dried with fires, none with spirit, but ten minutes is rather a short time for the whole process. We are sorry your query has been overlooked.

**S. E.**—We have often found such stains yield to ammonium persulphate crystals rubbed on wet.

**J. J. D.**—We believe these results are being produced by local chemical toning, by means of a brush. The hair, for example, is bleached with the ferricyanide-bromide solution, and the whole print then placed in a sulphide bath. If you examine the print closely you can see evidences (the lady's left shoulder) of the toning process having extended beyond its proper sphere. We advise you to get Somerville's "Toning Bromides," and try one or two of the processes, thickening the solutions somewhat with glycerine.

**SULPHOCYANIDE POISON.**—Is sulphocyanide of ammonia, used in toning P.O.P., poisonous like the cyanides? What is the least quantity which produces such symptoms? What is its antidote?—B. O. J.

It is not a highly poisonous substance. Potassic sulphocyanide, if subcutaneously injected, causes at first local paralysis of the muscles, and later, convulsions.

**UNLAWFUL USE OF PORTRAIT.**—I shall esteem it a great favour if you will enlighten me on the following little matter. Some little while ago I took the portrait of a lady, well known in this neighbourhood. She was so well pleased with it that she ordered an enlargement. When it was done my canvasser, unknown to me, used it for two or three days as a specimen, as it was so good a piece of work and the lady so well known. The portrait was then sent home with the bill. The lady then sent me an indignant letter, saying that she would not think of paying for a portrait of herself which I had hawked all about the district, and even went so far as to say she should consult her solicitor on the matter, as it had caused her great annoyance.—A. R. C.

One can hardly be surprised at the lady's annoyance at such unwarrantable use being made of her portrait. You say that your canvasser used the portrait without your consent, but that makes no difference, as you are responsible for your agent's action. It is illegal for a photographer to use portraits of his sitters for purposes of his own, and if he does he may find himself in trouble. We should advise you to at once explain the matter to the lady and make an abject apology, when she may possibly forgo legal proceedings.

**STEREO TRANSPARENCIES.**—I have recently seen some extraordinary fine stereoscopic pictures, that must have been taken many years ago. They are transparencies on glass, and bear the name of "Ferrier, Paris." The sight of these pictures has quite enchanted me, and I am anxious to go in for stereoscopic photography. I am told that these pictures can be done with the ordinary quarter-plate camera, and that a bi-lens one is quite unnecessary. Will you please tell me if that is the case? If so, how is it done? Also, what kind of negative is best for stereoscopic pictures?—AMBITIOUS.

A quarter-plate camera will do quite well for stereoscopic pictures. All that is required is to shift the camera horizontally two and a half to three inches between taking the two negatives. This is best done by having a small board to screw on the top of the tripod stand, with a fillet of wood back and front, between which the camera will slide, so that it is kept parallel at the two exposures. It need not be said that this arrangement will not do for taking moving objects. For such subjects a bi-lens camera is essential. Negatives for stereo pictures should be of a rather soft and delicate character. If they are made very vigorous the prints are apt to appear chalky when seen in the stereoscope.

**A QUESTION OF OBSTRUCTED LIGHT.**—I propose putting up a studio in my garden for professional work (portraits). I have had plans prepared which have been approved by the Council surveyor. My next door neighbour hearing of this is very indignant, and threatens to make me pull the place down if it is put up, as it will stop out the light from his side building. This is an out-building with two small windows in it, and is only occasionally in use. I have asked my solicitor about it, and he does not seem to care to give a decided opinion on the matter. Will you be good enough to give me yours?—R. WADE.

If your solicitor, who knows all the particulars, cannot give you advice we do not see very well how we, who only know what is

said in your letter, can do so. We may, however, tell you that if your neighbour cannot claim the privilege of "Ancient lights"—that is, his windows have enjoyed an unobstructed light for twenty years—he cannot do what he threatens. He can, however, put up a hoarding in his own ground that will stop off the side light from the studio, and you will not be able to prevent him. If he does enjoy "Ancient lights," he can stop your building if it obstructs so much of his light as not to allow him sufficient for his purpose.

**STAINED PRINTS.**—We are much troubled with stains on our prints, particularly with the vignettes. You will notice they are of a dirty pinkish tint and very unlike the yellow stains one gets from imperfect fixation or washing. It is only quite lately we have been troubled in this way, and we may say that it is only in the mounted pictures that the stains show, which they sometimes do directly they are mounted. This leads us to suspect that the mounts may be the cause, which is partly confirmed by the fact that it is only since we took this batch of chocolate mounts into use that we have noticed the stains. We enclose a sample of the mounts for you to see.—M. AND CO.

On examining the mounts we have no hesitation in saying that the trouble is due to them. One of the pigments used in the colouring for the mounts is soluble in water, as will be seen if they are wetted and a piece of white paper is rubbed against the surface. It will at once become tinted. If you continue to use the mounts, mount the prints dry, and use as thick and dry a mountant as you can. You would be quite justified in returning the mounts as being unsuitable for their purpose.

**PROSPECTIVE.**—The design A (ridge roof) and B (lean-to) are both good for portraiture, and opinions are very divided as to which is the best. It is very much a matter of opinion. The design C we should not recommend for portraiture, though it is very suitable for copying or reproduction purposes. Of course, good portraits could be taken in a studio of this form, but it requires more skill in working than either of the others, and therefore is not so well suited for a novice.

**COLD VARNISH.**—Last summer, when watching an itinerant photographer at work taking portraits on glass on the beach, I saw him varnish some of the pictures. The varnish he used seemed nearly colourless. It was simply poured over the plate, without heating, and appeared to dry in a few minutes. I asked the man what varnish it was, and he told me he made it himself, and it was his secret. It seemed to me that such a varnish would be very convenient to many of us for varnishing negatives. Can you give me any idea of what it is composed?—A.L.F. BRIDGEWAY.

The varnish that is usually employed for glass positives is a dammar varnish, and that was no doubt what you saw being used. It may be made by simply dissolving dammar resin in benzole, in about the proportion of thirty grains to the ounce of solvent. It is a very convenient preparation, but negatives varnished with it will not bear rough usage.

**BROKEN PLATES.**—Several times when I have bought plates at the dealers'—they have been half-plates—I have found one or two in the packet broken, and when that has been the case one or two more scratched by the broken glass. When this happens, to whom should I look for compensation—the dealer from whom I had them or the makers? It is a loss to have a dozen plates with two or three of them that cannot be used.—INQUIRER.

It would certainly be of no use applying to the makers, as you have had no dealings with them. Further, they take no responsibilities after the plates leave their works. The dealer also, we should say, would decline to make any recompense. Your experience seems to us to be exceptional, for, though we use a good number of plates by all makers, we very rarely meet with a broken one.

**S. J. J.**—Unless you had a written agreement, duly stamped, to the effect that, in the event of his leaving you, he was not to set up business within a certain radius of your place, you can, of course, do nothing. The man is entitled to do what he likes after leaving your employ, and it would be hard upon him if he could not.

**GLASS POSITIVES.**—I want to take, at a forthcoming fête which is being got up for a charitable purpose, some glass positives. These I shall charge for and the money taken handed over to the fund. I can manage to work the process fairly well, and hope to work it better by the time the affair comes off. What I want to know

now is, how can I make the plates more sensitive, as compared with extra rapid dry plates—are very slow? Is to increase the strength of the silver bath to, say, sixty grains the ounce—I am now using thirty grains—would that double the rapidity? I am using ———'s collodion.—POSTUMUS.

There will be no advantage whatever in increasing the of the sensitising bath above thirty or thirty-five grains the ounce as regards rapidity. With a stronger bath than will not get such good whites or such good results generally, compared with gelatine, the collodion is a slow process, and it is not to be helped.

**REVERSED NEGATIVES.**—I am asked to quote by a manufacturer for taking a number of negatives for illustrating a catalogue are to measure, clear, 8 x 6, and must be reversed as regards right and left, as they are to be used for some mechanical purpose. I shall be obliged if you will be so good as to tell me what will be the best for me to get—a reversing mirror or a glass, whether it would do to take the negatives though the course making proper allowance for its thickness in the focus.—T. WALTHER.

So far as results are concerned, there is no difference between a mirror and a prism, supposing them to be of equally good quality. Mirrors have the disadvantage that they occasionally may be re-silvered, and also are more liable to get damaged. Prisms are cheaper to purchase than are prisms, particularly if of large size. Large prisms are rather costly. Good reversed negatives can be taken through glass, but it is manifest that any defects such as specks, air bubbles, and the like, will show in the negatives and sometimes spoil them.

**PATENT AND REGISTRATION.**—I have invented a special plate arrangement, and I want to protect it so that it cannot be copied. What is the best way of registering it, as I do not go to the cost of a patent until I see whether the thing is worth it? Then, if it does, I shall patent it.—HANTS.

There is no form of registration that will give you protection in an invention of that kind. That can only be secured by a patent. You can obtain a provisional protection for £1, which will last for six months before the complete specification need be made. During that period you can decide what you will do. If you put on the market before it is patented it cannot be patented afterwards, as you seem to infer in the postscript to your letter.

**TERMINATION OF LEASE.**—I hold the above premises on a lease, which expires next September. The business is not a success, and I do not, of course, wish to leave, but the landlord has not given me a six months' notice. What I should like to know is, how I stand, as I want to keep on the place. What notice must be given me if he does not want me to continue?—ANXIOUS.

At the expiration of the lease the tenancy ceases, and there is no necessity for the landlord to serve you with notice. You leave as a matter of course, unless you arrange for a new term. It does not look like good business tact on your part to make the arrangements for a new lease until only a few months before the expiry of the current one. The landlord, if he grants a fresh lease, can make what terms he likes, and may position the rent, and you cannot help yourself.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what portion of the paper.

## The British Journal of Photography

The Oldest Photographic Journal in the World.

### SUMMARY.

**Photographic Convention.**—The report of the latter part of the Convention over which Sir Cecil Hertset has presided with great success is given on page 544. The group of members of the Convention is presented as a supplement to this week's issue. The key to the portraits will be published next week.

**Diamidophenol Developer.**—We commence the translation of the methods and formulae for this developer advocated by M. G. Balagny, by whom it is recommended as a universal solution for development papers, and lantern slides. Some of the essentials of M. Balagny's practice are the subject of some of our editorial articles. (Pp. 543 and 546.)

**Commercial Record Photography.**—The recent survey of St. College, Oxford, carried out by Mr. A. E. Walsham, is the subject of an article on page 549.

**Use of cerium instead of chromium salts for bichromate printing.** has been patented. Focussing mechanism, roller-blind, and printing frames and reversing backs are among other subjects of the week. (P. 552.)

**Owen Wheeler,** in a recent paper on instantaneous telegraphy, advises as to the most useful aperture of the lens, and the best form of camera for such work. (P. 548.)

**Descriptions and two illustrations of a modern country studio** interest those who may be building or renovating their studios. (P. 550.)

**Professor R. W. Wood** has recommended preliminary fogging of lantern taking negatives of faint spectra. The same expedient may be used for the photography of other badly illuminated objects. (P. 542.)

**F. Novak,** of the Vienna School of Graphic Arts, has published formulae for the making of slow-burning magnesium powders. (P. 543.)

**Precautions which too frequently are not taken in the framing of pictures** are the subject of some practical hints. (P. 543.)

**Particulars have been announced of the Optical Convention to be held next year.** (P. 554.)

### EX CATHEDRA.

#### The Permanency of Photographic Records.

It has been stated that Herr Thiele, of Copenhagen, has found that astronomical negatives are liable to variations that are of undoubted reality and seriousness, especially in the case of images of double stars. The apparent distances and relative positions of the stars appear to vary after a certain time, and sometimes two plates that have been exposed at the same time give differing records. This sounds very alarming, but possibly the report rather exaggerates the true state of affairs. Still, it is obvious that gelatine is liable to changes, and that it is by no means an ideal substance for holding a permanent record. Some little time ago we had occasion to go through a number of ordinary negatives about fifteen years old. We knew that every care had been taken in the preparation of the negatives, and that fixing and washing had always been properly carried out, yet, out of the four or five hundred examined, only a small proportion were in perfect printing condition. Strange markings had developed, especially in the skies, and various spots and mottlings were apparent on many of the negatives. The varnished ones, which were too few, escaped these troubles, which fact pointed pretty clearly to some form of decomposition of the gelatine set up by atmospheric influences. Numbers of valuable star chart plates were once lost at the Royal observatory from a very similar cause. Varnish is evidently a protection, but it is not certain that it is a permanent one, and in any case a glass plate is liable to breakage. The most desirable form of permanent record would probably be a photo-etched metal plate, but we are doubtful whether this idea has ever been tested.

#### The Photographic Salon.

From the prospectus of the forthcoming Salon we learn that this year's exhibition is to be held from September 11 to October 24, in the gallery of the Society of Painters in Water-Colours, 5a, Pall Mall East. As in recent years, we find the clause to the effect that pictures sent for exhibition to any other exhibition open in London at the same period will be disqualified. We quite sympathise with the desire of the Salon Committee to avoid duplication of pictures at the two contemporaneous exhibitions. Our only quarrel is with their form of expression. Of course, they can only depend on the bona fides of the exhibitor, and it would, to say the least, have been better to have said so. Another innovation in the Salon arrangements is the request for particulars of the number of copies obtainable of any exhibited picture. The Salon Committee rightly take the view that if the number of copies is strictly limited the value of the photograph is greater, and that the adoption of such a practice must generally enhance photographs as works of art in the eyes of the purchasing
